When we arrived at Liuminying Production Brigade, we saw that every one of the more than 150 households in the brigade had installed a solar energy hot water device. When commune members came home from work, they would take a comfortable bath first. Happily, they said to the correspondents, "We didn't spend much money for this apparatus (each one costs 50 yuan, but commune members paid only 20 yuan, the remainder being subsidized by the brigade), but it really solved a big problem for us." Now, these hot water devices have struck root in one commune and brigade after another in Daxing County.

In order that solar energy will be widely applied to agricultural production, with the cooperation of units and departments concerned, the Daxing County Science Committee has designed and fabricated for rural communes and production brigades solar energy devices having multiple uses. One such has been a piece of equipment that can dry grain, or be used in a greenhouse to grow vegetables or propagate seedlings, and can be used to heat bath water, which was put up in Ercunsan Brigade of Qingyundian Commune in June, 1979. Useable throughout the year, during last year's wheat harvest alone, it dried 280,000 jin of wheat. Now, the Daxing County Science Committee's comrades are striving to move ahead, determined to make new achievements in the multiple uses of solar energy.

Use With Flue-Cured Tobacco

Beijing GUANGMING RIBAO inChinese 21 Jul 81 p 2

[Article by HENAN RIBAO Correspondent Li Genlin [2621 2704 2651]]

[Text] Following 4 years of cooperative efforts on the part of the Changge County Tobacco Bureau in Henan Province, the Solar Energy Unit of the Institute of Dynamics of the Chinese Academy of Sciences, and the Tobacco Machine Unit of the Farm Machine Unit of the Farm Machine Institute of the Henan Provincial Machinery Bureau, "solar energy tobacco curing equipment" has been successfully developed at Dongzhuang in Changge County. This successful research has blazed a trail in the reform of flue-cured tobacco technology for savings in energy, lowering of production costs, and in improving quality of flue-cured tobacco.

The Dongzhuang solar energy tobacco curing equipment uses solar energy as a supplementary energy source. Atop massed ovens, solar energy heat concentrators and an associated hot air cycling system have been erected. The concentrators are of two types. One is a flat heat concentrator that uses glass as its transparent material, and the other is an arched heat concentrator that uses plastic sheeting as its transparent material. The heat efficiency rate of these two kinds of heat concentrators is 49.6 and 45.9 percent respectively as compared with a between 25 and 30 percent saving in coal for the massed ovens, and as compared with a 40 to 50 percent saving in coal for the native curing sheds. Quality of flue-cured tobacco is also better than that of either the native curing sheds or the massed oven building. This February the units concerned made an appraisal of this research achievement, concluding that the heat efficiency rate and coal conservation index of both the glass and plastic sheeting solar energy tobacco curing equipment's heat concentrators attained better standards than similar equipment used elsewhere in the county. The structure of the plastic sheeting heat concentrator was particularly simple, its costs of construction was low, and it could be easily promoted in other places.

In order to improve the solar energy tobacco curing equipment's utilization rate and put a single oven to multiple uses, the Changge County Tobacco Bureau launched further experimental research in multiple use with the vigorous support of provincial, prefecture, and county science committees, achieving heartening success in the hot air generating room for the solar energy tobacco curing equipment, they built an edible fungus cultivation room atop which was a glass hothouse. In the hot air generating room was a seven force axial flow wind machine able to supply hot air both to the flue-cured tobacco drying room and to the edible fungus culturing room. After the season for curing tobacco was over, the flue-cured tobacco drying room could be used to dry grain and other agricultural byproducts, and could also be used for drying Chinese vermicelli. This equipment could both raise and lower temperatures, and except for the winter season and the tobacco curing season, when it was necessary to have a fire, coal was otherwise not burned. During May, temperatures may drop to 12°C. Last year, the equipment was used to culture pinggu [1627 5466] [a kind of mushroom] for a harvest of 2,400 jin, the largest pinggu weighing 7.6 jin, and each jin of cotton husks producing 8 liang of pinggu. This spring, more than 10,000 jin of vermicelli were dried, and a harvest of more than 100 jin of garlic was taken in. Currently, hedgehog hydnum [Hydnum erinaceus], pinggu, white mushrooms, and vermicelli are being produced here.

Solar Energy, Biogas in Combination

Beijing GUANGMING RIBAO in Chinese 21 Jul 81 p 2

[Text] With the help of the energy laboratory of the Chinese Academy of Agricultural Engineering Design, the Mianyang County Science Committee in Hubei Province has achieved success with experiments in hot house culture using a combination of solar energy and biogas.

Mianyang County is located on the Han River Plain. Its climate is mild and rainfall copious, making it suitable for continuous cropping of early and late rice. Here seedling propagation for the early rice crop is done in open fields, and frequently spring season cold waves cause fairly serious seedling rot. In view of this situation, this county switched to seedling culture in hothouses heated by stoves. This was an effective method, but too many stalks and stems were burned, more than 4 jin of stalks and stems being required to propagate seedlings from 1 jin of rice seeds, which made it economically not worthwhile. In 1979, with the help of relevant units, the Mianyang County Science Committee began experiments using solar energy and biogas to grow seedlings.

Solar energy is an inexhaustible resource, its shortcoming being that when there are 2 or more days of overcast and rainy weather, the accumulated energy is used up, and a supplementary source of energy is needed. In Mianyang County, the best supplemental energy source is biogas. Finding a way in this resource of the county, the County Sceince Committee constructed a 100 square meter glass hothouse, a 100 square meter simple hot water concentrating pit, and a 90 cubic meter biogas pit. These facilities could mutually combine solar energy and biogas, using the advantages of one to make up for the disadvantages of the other.

Almost 3 years of experiments have shown that by using this method to propagate seedlings, early seedling growth is promoted and seedling survival is assured. It both saves conventional energy sources and permits diversification inside the hothouse. Using these facilities, 600 mu of early crop rice seedlings can be grown every year. Once the rice seedling propagation season is over, edible fungi such as pinggu and black wood fungus can be cultured, and some vegetables may be grown as well. The hot water may also be used for bathing or washing clothes. Looked at from an economic standpoint, the entire investment may be recovered within 4 years, making it suitable for promotion in rural communes and brigades.

BRIEFS

SOYBEAN MILK FROM SOLAR POWER--The Jiaonan County Fermentation Plant in Shandong Province with only 82 employees has successfully developed use of solar energy soybean milk manufacturing technology, thereby greatly increasing output of soybean milk. The process not only saves energy, but also cuts down on environmental pollution and improves sanitary conditions. Following appraisal by relevant units, this process is considered to have broad prospects for future development in the fermentation industry. This plant's soybean milk production technology had formerly been antiquated. It depended entirely on the use of several hundred large vats for open air fermentation to produce soybean milk. Annual output of soybean milk was 120,000 jin, far from enough to satisfy the needs of the widespread masses. Last year they studied the experiences of a fraternal unit in the use of solar energy, themselves then designing and building a set of flat solar energy heat concentrator equipment with a light collecting area of 238.7 square meters for use in producing soybean milk. This January experimental batch production began, and after a 3 month fermentation cycle, 225,000 jin of soybean milk has been produced. Chemical testing has shown that the first batch of soybean milk meets promulgated standards. [Text] [Beijing GUANGMING RIBAO in Chinese 21 Jul 81 p 2] 9432

ANHUI COAL MINES--Hefei, 3 Aug (XINHUA)--Seven pairs of large and medium-sized coal shafts, with a total annual capacity of 15 million tons, are now under construction in Anhui Province, according to the Huainan and Huaibei coal mining administrations. Coal washing plants, power plants, railways and public utilities for the mining areas are also being built, the administrations said. The Liuqiao coal mine, with an annual capacity of 600,000 tons, opened in May in Suixi County near Huaibei City. The Luling coal dressing plant, with an annual capacity of 1.8 million tons, opened in July in Suxian County. Construction of the Huainan and Huaibei coal fields, with verified reserves of more than 22,000 million tons, is one of China's key construction projects. STEPS FOR RAPID DEVELOPMENT OF CEMENT INDUSTRY OUTLINED

Beijing SHUINI /CEMENT/ in Chinese No 6 10 Jun 81 p 2-5

/Article by Ding Hong /0002 7703/, chief of the Bureau of Cement of the Ministry of Building Materials: "Opinions on Hastening the Development of Our Nation's Cement Industry"/

/Text/ Recently, the leading comrades on the State Council issued demands for the development of our nation's cement industry. They can be summarized in three points: 1. The cement industry must be oriented toward the 1 billion people, especially the 800 million farmers. 2. The development of building materials must follow the road of concrete. 3. The development of the cement industry must be hastened. Therefore, how to hasten the development of the cement industry on the presently available foundation is an important question that should be conscientiously studied at present. Now let me talk about my opinions regarding this question.

I. Present Situation of the Cement Industry

For 31 years, as the national economy developed, our nation's cement industry established a definite foundation. The production of cement increased from 680,000 tons in 1979 to 79.86 million tons at the end of 1980. Distribution has improved greatly. Of the 29 provinces, cities, and autonomous regions, all except Xizang and Ningxia have large and medium-size cement factories. Small cement factories are scattered throughout the nation. A relatively complete technical team possessing definite standards in geological survey, scientific research, design, education, machinery manufacturing, mine construction, building and installation, and production management has grown up. During the mid-1950's, the technical standards of our nation's cement industry were no lower than those of the Soviet Union. The technological and economic indicators of the wet-method rotary kiln and of the liboer /phonetic/ kiln surpassed the levels of the same types of kilns in the Soviet Union. In 1956 we began to study the dry-method rotary air preheating kiln, along with other nations of the world, and we were not late in developing new technology and new techniques. But later, because of the influence of leftist mistakes, and especially during the 10 years of upheaval, the foundation of the cement industry was damaged and progress slowed. At present, the level of equipment and technology of our nation's cement industry lags far behind the advanced nations of the world. The present situation in the cement industry has created many hindrances to the rapid development of the cement industry. Generally speaking, the foundation and strength are weak, the technological level is low, the equipment is backward, management is backward, the product structure is not rational, and the economic results are not good. To hasten the development of the cement industry, we must exert great efforts to solve these problems.

II. Small Cement Industries Must Develop Steadily During Readjustment

The small cement industry is an important force that cannot be neglected in the present cement industry. In 1980, the products of small cement plants constituted 68 percent of the total cement yield of the entire nation. They served greatly to alleviate the conflict between supply and demand for cement, especially in its orientation toward the farm villages to solve the needs of the 800 million farmers. But because most small cement factories have outdated equipment, their techniques are not complete. Therefore their technological strength is weak, the quality of their products is not sufficiently stable, and the cost and sales price are high. Therefore, this part of the enterprise must be readjusted, reorganized, improved, and rebuilt so that it will gradually develop into a superior quality, economical operation.

During the period of readjustment of the national economy, small cement manufacturing industries must solve two problems: One is to improve the quality of their products. Their products must meet the standards for quality established by the state for products of large and medium enterprises. Practice proves this can be done. At present, a fairly large portion of the enterprise has already achieved this goal. Foreign experience also proves that as long as techniques are complete and management is scientific, No 400 and No 500 cement can be produced in vertical kilns. The second is to reduce the cost of the products. Last year, we held three learning classes in economic accounting and cost management in order to help small factories learn economic accounting and improve operations, and we believe that after such efforts, the costs of small cement factories can be reduced.

In line with the spirit of readjustment of the national economy, no new small cement factories should be build in the future, except in a few faraway border regions. Presently existing enterprises should grasp technological reform tightly in the following aspects:

1. Ordinary vertical kilns should gradually be rebuilt into mechanized vertical kilns in order to increase production, improve quality, and lower energy consumption.

2. Presently available mechanized vertical kilns should be technically equipped as a complete set, and equal treatment of raw materials, semifinished products, and finished products should be strengthened to assure the need for steady production.

3. Utilization of surplus heat of rotary kilns over 2.4 meters in diameter that have already entered into production should be solved as a key measure to reduce heat loss in firing chamotte. Measures can be suited to local circumstances to utilize surplus heat for power generation for the rotary air preheater and vertical cylinder preheater, or to utilize surplus heat for drying. Dry-method hollow kilns of less than 2.4 meters in diameter consume a lot of energy, their technical and economic indicators are poor, and their development in the future should be limited.

Doing the work of rebuilding and improving small cement plants is a major way to increase the production of cement in the near future. The potential for this is very great. We must emphasize it and take forceful measures. First, we must grasp well the backbone enterprises that produce over 40,000 tons annually, so that small cement manufacturing enterprises can healthily develop on the basis of improving quality and improving their economic results.

III. Presently Available Large and Medium-Size Enterprises Are Important Foundations for Hastening the Development of the Cement Industry

The nation's 49 large and medium-size cement manufacturing enterprises are a very important backbone force of the cement industry. They are an important foundation for the future development of the cement industry. We must stand on this foundation before we can change the backward situation of the cement industry relatively quickly and with more conservative investment.

The distribution of the present cement industry is basically rational. The main problem is that the quantity of products of the large and medium-size cement plants is insufficient. Newly built enterprises cannot easily produce results within a short period for various reasons. Utilizing old plants for expansion and rebuilding will produce quicker results than building new plants.

The specific way to expand and rebuild old plants is as follows:

1. Enterprises with suitable conditions should be selected for enlargement of their facilities and expansion in the scale of their plants. Large facilities should be utilized. The investment per unit of product is lower than the investment in medium-size plants. The building period is shorter when compared to building several medium-size plants of an equivalent total scale. Therefore, new types of dry-method kilns can be expanded to a daily production capacity of 4,000 tons, 6,000 tons and even 8,000 tons at such cement plants as the Dalian, Huaxin, Zhongguo, and Jiangnan cement plants, which are old plants along rivers, near the seacoast, with good resources, and where transportation by sea and land is convenient; thus their production can be expanded from several hundred thousand tons at present to 2 or 3 million tons. To hasten the rate of expansion of old plants, key facilities of single unit machinery [whose development] cannot be solved within a short period domestically should be imported so that over a period of 5 years, through expansion, there can be increased production of about 10 million tons of cement.

2. Rebuilding of cement factories using the wet method should be grasped tightly. Sixty percent of our nation's large and medium-size enterprises use the wet method of production. The efficiency of the single unit machinery is low, energy consumption is high, and urgent reforms are needed. But because wet-method kilns are mostly small kilns with a diameter of less than 3.5 meters, changing the wet-method kilns to dry-method production still requires further study because, first, there are few usable parts, second, objective conditions do not allow discontinuation of production for rebuilding, and third, the technological and economic feasibility [of the changeover] requires further study. Therefore, wet-method plants should not hasten to rebuild facilities at present, but they should be rebuilt according to plan: for example, new dry-method production lines can be built alongside the original wet-method production lines, and for a certain period the new and old facilities should be allowed to coexist and the dry and wet production methods can be used together. We have proposed this method by starting out from the actual situation in our nation. Therefore it is more practical and effective. Experimental work in changing wet-method production should still be actively carried out, and the technological and economic results of rebuilding obtained through experiments should be evaluated of an overall basis so as to provide experience for future efforts to "change from the wet to the dry" method.

3. During the period of readjustment, forces should be organized to explore on an overall basis the conditions for rebuilding and expanding the old plants. On this basis, study the feasibility of plans to rebuild and expand enterprises that have suitable conditions, and propose overall and definite plans to rebuild or expand the plants so as to create conditions for a great development of the cement industry after readjustment.

Digging out the potential of old plants is an effective way to increase the production of cement within the near future. At present, we must grasp in a key way the following three aspects of work:

1. Enterprises which have not yet reached their designed capacity must quickly create conditions to reach that designed capacity. In general, the 49 large and medium-size enterprises are operating over capacity, but there are 10 plants that have not reached their designed capacity. The reason is that management is poor, there are a great number of loose ends left by capital construction, and, after entering into production, the enterprises cannot produce normally, and external conditions such as lack of coal, electricity, water and dregs and shipping difficulties mean that production needs cannot be assured. These 10 plants can increase their production by 1.05 million tons of cement after they reach their designed capacity.

2. Technical measures that have proven to be effective should be popularized in order to improve the efficiency of the facilities and conserve energy consumption. New types of fireproof lining materials should be used to extend the operating time of the cement kiln and improve operating efficiency, and heat-tolerant steel chains should be popularized to improve the heat-utilization efficiency of the cement kiln. Using these two measures can increase the production of cement by 2 to 3 percent on the present basis; this would be equivalent to an increase of 700,000 tons of cement each year. Ball grinders should be of wear-resistent steel, at this would conserve 10 kilowatt-hours of electricity for each ton of cement produced at present. Calculated at an annual production rate of 80 million tons of cement, this would mean a saving of 800 million kilowatt-hours of electricity.

Reducing the burning temperature of chamotte is a promising measure for increasing yields and conserving energy. At present, scientific and research departments have already obtained welcome results from their experiments. A reduction of 100°C to 150°C in temperature in the burning of chamotte can produce an increase of about 10 percent in yield and conserve 8 percent of the fuel, but further in-depth research into production techniques and into the properties of the products is still needed. After evaluation, this can be gradually popularized among enterprises with suitable conditions.

3. Deficiencies should be corrected in order to improve the comprehensive productive capacity. During recent years, four large and medium-size enterprises expanded one production line, but because a whole procedure was lacking, a comprehensive productive capability was not formed. If the deficiencies can be corrected, the productive capacity of cement production can be increased by 500,000 tons.

After implementation of the measures to dig out the potential in old factories, an increase of about 2.2 million tons of cement a year can be realized.

IV. Newly Built Plants Should Engage Mainly in Dry-Method Production

After many years, the debate between the wet and dry methods have now been decided, and the dry method is the direction of future development. The problem is that our dry-method facilities are still technologically incomplete, and they have not yet reached the point of popular use. Therefore, the most urgent task at present is to concentrate scientific and research and design efforts to come up with several dry-method facilities and plant designs that are technologically more complete for selection at the time the plants are constructed. Design work on a dry-method production line with a daily productive capacity of 2,000 tons has made great progress after several years of effort, but there are still more technical links that require further research and solution. It is suggested that the ministry establish a specialized internal agency to coordinate research, design, equipment manufacturing, and experiments for a production line with a daily capacity of 2,000 tons in order to realize completion of the experimental design work for the entire mainframe machinery and equipment set within a year. At the same time, fixed localities should be grasped tightly to build up the work in about 4 years, summarize experience, and rapidly popularize it. The external decomposition kilns with diameter of 3 x 48 meters, and the 4 x 60 meter diameter rotary air preheating kiln and vertical cylinder preheating kiln, which have already been built or are being built, must be perfected in order to create conditions for the utilization of the dry-method technique by newly built plants and rebuilt old plants of various scales.

The type of kiln for the newly built dry-method plants can be selected by suiting measures to local circumstances. The general direction is to increase production and conserve energy. But in regions where there is a shortage of electric power, the dry-method hollow kiln with a surplus heat generator can be used. The efficiency of electric power generation is not comparable to that at large powerplants, but given our nation's conditions, in which the price of coal is cheap, the price of electricity is expensive, and there is a shortage of electric power supply, efforts which can solve the source of electricity and can also produce economic gains are still rational for enterprises. The dry-method hollow kiln that uses surplus heat to generate electricity actually consumes about 1,050 kilocalories of heat per ton of chamotte, calculated on the basis of a need for 0.425 kilograms of coal to produce 1 kilowatt-hour of electricity, and deducting the amount of coal used for the generation of electricity, and deducting the amount of coal used for the generation of electricity. This is still a type of kiln that at present has a relatively low consumption of energy in our nation.

V. Establish Chamotte Production Bases; Disperse Cement-Grinding Plants; Supply Users With Unpackaged Cement

Large chamotte production bases should be established in regions where mineral resources are rich and transportation is convenient. Grinding stations should be established in large and medium-size cities and regions where there are no mineral resources and where the amount of cement used is relatively large. Consumers should be supplied with unpackaged cement. This is an important economic reform that has a direction for development. Its main benefits are as follows:

1. It solves the problem of supply and demand for cement in regions where limestone resources are not available. It changes the present situation of shipping limestone and cement over long distances to certain localities and reduces the burden of shipping.

2. Unpackaged supplies can conserve the use of massive quantities of paper for packaging, and a massive quantity of superior timber materials can be conserved. Calculated at an annual production of 120 million tons of cement, 3.6 million cubic meters of Korean pine and pinus bungeana would have to be used each year to produce the paper bags for packaging the cement. It can be seen that it is very necessary to supply unpackaged cement in China where timber resources are in short supply.

3. It benefits improvement of environmental pollution in large and medium-size cities.

4. It benefits the rebuilding and improvement of some small plants. Shipping a part of the chamotte to small plants and vertical kiln chamotte mixing and grinding plants to produce cement along the sides of transportation routes, or converting some small plants into grinding stations, will be beneficial to improving quality and reducing cost.

Under the present system, implementing this measure requires that the state arrange for investment in and construction of a group of large commercial chamotte bases. At the same time, corresponding and rational regulations must be established for the distribution of cement, the pricing of chamotte, and tax policies so that the chamotte bases, grinding stations, and localities will all benefit. The method is first to grasp a trial locality. For example, the state can invest in and build a chamotte production line at the Dalian Cement Plant in Tianjin; the locality can invest in the building of a grinding station (Tianjin does not have good limestone mines); the Dalian chamotte can be shipped by boat to Tianjin for grinding; and unpackaged cement can be supplied locally. After experience has been obtained, this method can be popularized.

VI. Readjust the Product Structure of the Cement Industry

At present, the structure of cement products has two relatively outstanding problems. One is the large proportion of medium-label /quality/ cement and the scarce amount of high-label /quality/ cement and low-label /quality/ cement suitable for building mortar. The second is that the proportion of the products of large, medium, and small enterprises is not rational; the proportion of products of large and medium enterprises with good economic results is too small. These two problems should be readjusted during future development.

1. We should increase the proportion of high-label cement and special cement, and at the same time develop a portion of low-label building cement. Doing this will benefit the rational utilization of cement, achieve the goal of conserving the amount of cement used, reduce the burden on shipping, and conserve packaging materials. This will also create the necessary conditions for the development of high-label concrete to improve the standards of building structures and construction technology. We imagine that after readjustment, presently existing large and medium-size enterprises will for the most part provide high-quality cement above the 600

label to society; small enterprises will produce mainly No 400 and No 500 medium-quality cement; and in regions where there is industrial waste, and near large construction sites in cities, we can allow some small plants to produce building cement of No 250 and No 300 grades, which contain less chamotte. To do this readjustment work well, the following problems must be solved well.

(1) When the state arranges production plans for large and medium-size enterprises, it should consider the effects brought about by a change in the variety of products and appropriately reduce production goals. After the product structure is readjusted, utilization will be more rational, there will be more conservation, and the products therefore will be more beneficial to the state. Problems must be considered on an overall basis, and efforts should not simply be to pursue production goals.

(2) We must have a rational pricing policy and a tax policy so that the production enterprises and the consumers will both benefit from the economic gain to different degrees through readjustment of the product variety.

(3) The work of the design and construction departments must be strengthened in order to rationally utilize different varieties and labels of cement.

(4) We should do the work of propagandizing and popularizing the production of high-label concrete well.

2. We should select small plants with good conditions for expansion into large and medium-size enterprises, so as to increase the backbone elements of our nation's cement industry. At present, the quantity of products produced by the large and medium-size enterprises cannot satisfy the needs for construction of large industries. Increasing the proportion of the products of large and medium-size enterprises cannot passively limit the development of small cement-producing industries. The development of large and medium-size enterprises should be hastened, and some small plants should be expanded and rebuilt and upgraded to large or medium-size plants. Two years ago, there were projects to upgrade 22 small plants, but for various reasons most /projects/ have been terminated or postponed. Some /plants/ would have better conditions after implementation, and in the future this should be reconsidered. Presently existing small enterprises with good product quality and with a rational economy should be encouraged to develop. The necessary administrative measures should be taken to intervene in those plants that do not have productive conditions and that produce low-quality products for long periods. Some should be readjusted within a certain period of time, while those that really do not have /the proper/ conditions can be converted to grinding stations. We can imagine that after a definite period of readjustment, the proportion of products of large and medium-size enterprises can be increased to about 50 percent.

VII. Strengthen Basic Work

Scientific research, education, design, equipment manufacturing, geological survey, specialized installation, mine construction, and production management teams must be rapidly strengthened. To hasten the development of the cement industry without a strong and forceful team of workers consisting of scientific research and design personnel is not possible. Faster and better development is possible only when the foundation is well established. The function of technical personnel must be fully developed. In technical problems, technical personnel should have their duties, their authority, and their responsibilities so that they can fully develop their technical skills. We must strengthen the training of workers and elevate their cultural, scientific, and technical level. We must emphasize the development and construction of the resources of mines for cement, strengthen surveys of mines, and strengthen the design forces. We must improve the standards of equipment manufacturing. Equipment manufacturing is a key to whether or not development of the cement industry can be hastened and whether the technical level will be high or low. Without modernized equipment, it will not be possible to have modernized cement plants. To improve the standards of equipment manufacturing and the standards of complete sets of equipment in our nation as quickly as possible, besides developing our own nation's technology we should plan for the introduction of foreign, advanced, reliable, and suitable technology and necessary single machinery units into our nation.

VIII. Actively and Steadily Carry Out Reform of the Economic Management System

The present system in the cement industry hinders the development of productivity. Hastening the development of the cement industry requires a reform of the system. We must actively create conditions to establish a management system under which responsibility is both centralized and delegated to different levels. There must be a clear responsibility system. The present situation whereby there are people in management but there is nobody to take responsibility should be changed. The cement industry must be specialized; it must centralize the forces of scientific research, design, equipment manufacturing, and geology to form a company. Unnecessary centralization will not produce strength or high efficiency.

Now, the leading comrades of the Party Central Committee and the State Council care about and are paying attention to the development of the cement industry. This is a very favorable condition. As long as we conscientiously implement the line of the Third Plenum, as long as the direction is correct, as long as the measures are practical and useful, and as long as we do not just talk and issue written orders but concretely work, I believe that after a definite period of effort, our nation's cement industry will undergo a relatively great improvement in the relationship of supply and demand and in the situation of the industry. The gap between our level and the world's advanced level will greatly lessen. Let us take action together to promote the development of our nation's cement industry, and welcome new victories.

RURAL MARKET SURVEY RESULTS ON BICYCLES, SEWING MACHINES, WATCHES

Beijing ZHONGGUO CAIMAO BAO in Chinese 11 Jun 81 p 4

[Article: "How Many Bicycles, Sewing Machines and Wristwatches Are Needed in Rural Villages? Survey Shows That This Year an Average of 1 Out of Every 55 People Wants To Buy a Bicycle; an Average 1 Out of Every 16.5 Households Want to Buy a Sewing Machine, and an Average of 1 Out of Every 88 People Wants to Buy a Wristwatch"]

[Text] Recently the National Supply and Marketing Cooperative Administration's Planning Bureau had its contact points in rural markets in 26 provinces, municipalities, and autonomous regions survey peasant needs for bicycles, sewing machines, and wristwatches.

Statistics from 86 contact points on 1,258,000 households and 6,670,000 people showed that as of the end of 1980, there were 422,000 bicycles, or an average of 1 bicycle for every 14.6 people, and 184,000 sewing machines, or 1 sewing machine for every 6.9 households. In 1981, 114,465 bicycles will be needed, or an average of 1 bicycle per 54.9 people; and 78,077 sewing machines will be needed, for an average of 1 sewing machine for every 16.52 households. Extrapolating these figures, in 1981, rural villages nationwide will require 15.66 million bicycles, and 11.16 million sewing machines. By 1985, there will be 1 bicycle for every eight people in rural villages, and 1 sewing machine for every 2.5 households.

A look at the circumstances of the survey shows that since economic conditions differed from place to place, requirements for bicycles and sewing machines differed too. In places with good economic conditions, the number owned was large and the number required was large too. In plains areas and places with fairly good economic conditions, the number required also increased very rapidly. In places where the economy is not well developed or where consumption levels are low, the number currently owned is small and requirements are comparatively small. However, in terms of development, a greater potential exists for purchases in such places.

In the course of the survey, commune members had many complaints about the supply of bicycles and sewing machines. First was that the number supplied to rural villages was too few. In recent years rural purchasing power has risen rapidly; nevertheless, the proportion of supply to rural villages has steadily declined. In 1978, for example, bicycles supplied to rural villages accounted for 36.65 percent of total output. In 1979, this declined to 35.58 percent, and in 1980, it declined further to 30.72 percent. Surveys done by the 86 contact points showed that in 1980 supply to rural villages of bicycles and sewing machines amounted to only 40 percent and 30 percent respectively of the number required. Second was the need for sturdiness, durability, and good quality. In 80 percent of the places surveyed, people wanted heavier bicycles, and they also wanted name brands.

According to statistics on 6.06 million people at the 86 contact points, as of the end of 1980, people owned 530,000 wristwatches, or an average of 1 watch per 11.4 people. The ownership pattern was very uneven, however. In the suburbs of large cities, virtually everyone had a wristwatch. In the suburbs of Beijing and Shanghai, for example, there was an average of 1 watch for every 1 plus people. In these places, the main purchases of the future will accompany increase in population. In places where incomes were relatively high, commune members had a relatively large number of watches, particularly young people. In places where incomes were not high, it was mostly cadres, employees and staff of enterprises, and teachers; few commune members had watches. In Jiuzhou District of Huangping County in Guizhou Province, for example, except in government organizations where personnel had almost 1 watch per person, among commune members, there was only a single wristwatch per every 500 people or so. At these 86 contact points, in 1981, 70,000 wristwatches will be needed for an average of 1 watch per 88.1 people. Extrapolation from this figure shows that in 1981, 8 million wristwatches will be needed in the rural villages of the country. By 1985, there will be an average of 1 wristwatch for every 9.4 people.

The tendency shows that future needs for wristwatches will be most in places where economic conditions are good. The peasants like Chinese made mechanical wristwatches, particularly those made in Shanghai of medium quality and selling for about 60 yuan. Furthermore, a certain ratio of women's watches is required A survey done in Yukang County in Zhejiang Province shows that 30 percent of the watches people want to buy are of medium size and 10 percent are of small size.

COOPERATIVE VENTURES USING FOREIGN CAPITAL ELABORATED

Guangzhou GUANGZHOU RIBAO in Chinese 12 Jul 81 p 1

[Article: "Remarkable Achievements in Foreign Economic Work of Guangzhou Financial and Trade System; Creates Large Amount of Foreign Exchange for the Country; Creates Conditions For Increased Employment"]

[Text] Since the last half of 1979, Guangzhou's finance and trade system has instituted "special policies and flexible measures" in its foreign economic work. By launching cooperative ventures, processing of goods brought into China from abroad, engaging in compensatory trade and barter trade, and such flexible and diversified measures, it has used foreign capital for the introduction of advanced technology. According to statistics, formal contracts have been signed and implemented for a total of 44 projects, of which 14 have to do with cooperative development of tourism, 15 have to do with repair and maintenance of goods, 4 concern introduction of advanced equipment for the development of production of foodstuffs, 4 concern importation of materials from abroad for processing, 6 involve technical exchange, and 1 involves export of labor. In total, they employ more than S77 million of foreign funds, and have already created more than $5.6 million in foreign exchange for the country and made employment for more than 1000 people.

The finance and trade system's use of foreign capital for the introduction of advanced technology has made heartening changes in the countenance of some enterprises. First tourist facilities began gradually to improve. Since 1979 the Orient Guesthouse has used more than 32 million Hong Kong dollars to make changes that have converted it into a first rate guesthouse meeting international standards while maintaining a Chinese atmosphere. It has been favorably commented upon by both Chinese and foreign guests. In addition to stepped up cooperation with the Hong Kong Xin Hecheng Company, Ltd. in preparing to construct the China (Guangzhou) Hotel, the municipal finance and trade system is also actively using foreign capital to improve Mineral Springs Villa, People's Mansions, the Guangzhou Guesthouse, and food and beverage service industries in order to meet the ever increasing needs of developing tourism.

Financial and trade departments have used foreign economic cooperation to operate goods maintenance and repair service centers, which has increased the city's technical forces for maintenance and repair of goods. Timepiece and eyeglass firms have benefitted and been strengthened. The Southeast Timepiece Shop and the

Zhongshan Fifth Road Department Store have worked with foreign traders to operate timepiece maintenance and repair services, thereby raising standards in electric quartz crystal watch repair. The Youguang Eyeglasses Shop on Renmin Nanlu has begun to run a computerized eye examination and lens prescription service, and the Jingyi Eyeglasses Shop on Zhongshan Fifth Road has set up a computerized contact lens examination and prescription center. Foreign cooperation in opening maintenance and repair service businesses requires small investment of capital, produces results quickly, and provides large benefits.

The Municipal financial and trade system is also giving attention to use of advanced foreign technology to improve upon commercially operated industries, giving new life to some old enterprises. The Yongcheng Bedding Cooperative belonging to the Municipal Textile Company possessed only simple equipment and its production methods were backward. It has since introduced advanced clothing processing technology, valued at 700,000 Hong Kong dollars, to establish a clothing production assembly line of a certain size, rapidly transforming the enterprise's backward condition.

While giving attention to supplying the domestic market, the municipal financial and trade departments have actively worked with foreign trade departments in efforts to expand exports. The Municipal Supply and Marketing Trust trade warehouse alone supplied 15,000 tons of dried fruits and miscellaneous foodstuffs outside of plan to foreign trade units during the past year, producing more than $5 million in foreign exchange. Goods purchased for trade supplied to foreign trade units by the financial and trade system have steadily increased. In 1980 goods purchased for supply to foreign trade units amounted to more than 73 million yuan, a 32.8 percent increase over 1979. Goods purchased for export between January and May this year amounted to 38.11 million yuan, for a 17.7 percent increase over the same period last year.

Municipal finance and trade units have also worked hard on supplying foreign markets and supplying overseas Chinese goods. In recent years, the Guangzhou Friendship Company's, the Foreign Ship Supply Company's, and the Overseas Chinese Goods Supply Company's business has multiplied, while at the same time international tourism and international advertising has steadily developed, thereby creating more foreign exchange for the country. According to incomplete statistics, foreign exchange created by the municipal finance and trade system during 1980 amounted to more than $26 million (exclusive of earnings from overseas Chinese remittances).

In accordance with overall actions taken in readjustment of the national economy, the municipal finance and trade units have closely linked development of foreign economic work and enlivening of domestic markets. During the past year or more, they have used local foreign exchange and their own outlays of foreign exchange to import raw materials and goods that are urgently needed in China to support industrial and agricultural production, and to increase the supply of goods so that the state could get back a large amount of currency and increase revenues.

GUANGDONG LEADER RELAYS CENTRAL VIEWS ON SPECIAL ZONES

HK010203 Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 31 Jul 81

[Text] Following the fourth enlarged plenary session of the fourth Guangdong provincial CCP committee, the provincial CCP committee held a forum of prefectural and municipal CCP secretaries from 27 to 29 July to convey, study and implement the spirit of the recent central work conference on Guangdong and Fujian Provinces and on the special economic zones. The forum held: At present, while seriously studying and implementing the spirit of the sixth plenary session, we must in connection study and implement well the spirit of the central conference, continue to carry out the special policies and flexible measures in light of the province's reality, open up to the outside world, relax the internal policies, hand down power to the lower levels, and boldly carry out reforms, to make the province's economy still livelier and do still better in building the special zones.

Provincial CCP committee First Secretary Ren Zhongyi presided at the forum. Provincial CCP committee Secretary Liu Tianfu conveyed the spirit of the conference convened by the State Council on Guangdong and Fujian Provinces and on the special economic zones. He said: This meeting fully affirmed the achievements of Guangdong and Fujian Provinces in the past 2 years in implementing the special policies and flexible measures stipulated by the central authorities. The State Council conference pointed out: Practice has proven that the central policy decision to institute special policies and flexible measures in Guangdong and Fujian Provinces and to set up special economic zones there is correct. This State Council meeting also briefly summarized the main contents of the special policies and flexible measures instituted in the two provinces, as follows: 1) open up still more to the outside world. This includes actively making use of overseas Chinese and foreign investment, introducing and using advanced technology and scientific management methods and expanding foreign trade; 2) relax the internal policies more. This includes permitting the coexistence of many types of economic components under the leadership of the socialist economy, making better use of the law of values and various economic levers and making the economy still more lively; 3) expand the powers of the two provinces, including their powers in economic matters, personnel, and local legislation, and enterprise decisionmaking powers. This in brief means opening up to the outside world, relaxing the internal policies, and handing down power to the lower levels. This demands bringing the superior features of the two provinces into play and speeding up their construction, so that the two provinces can become rich before others and also probe experiences for reforming the economic system in the whole country.

The forum initially studied the guiding ideology and demands for implementing the spirit of the State Council conference in Guangdong:

1. It is necessary to be bold in experimenting and pioneering new things. At present the whole country is carrying out reforms of the system, and Guangdong must advance ahead of the others and strive to accomplish modernization a bit earlier than other places.

2. It is necessary to overcome bureaucratism. Stress must be on efficiency in our action. As the central authorities have expanded Guangdong's powers, we must be skillful in using them. We must in all cases improve our work efficiency, whether in seeking instructions on work from higher authority, or in carrying out external economic dealings, or in cooperating with fraternal provinces and municipalities. Approval, action, and results must be swift.

3. It is necessary to act with caution, bear the whole situation in mind, and pay attention to the effects of our work, so that the central authorities can feel at ease. In the course of using the special policies and flexible measures stipulated by the central authorities and in running the special economic zones, we must take account of the interests of the state, the collective and the individual and also of our neighbors. Our main way of striving to become rich before others is to develop production and foreign trade. On the basis of developing production we should enable the masses to increase income and make our market supplies more abundant. We must take resolute action to oppose graft and corruption. We must stress trust and socialist business morality, and oppose vicious behavior of resorting to unscrupulous methods in order to make money.

4. The special economic zones must be run strictly according to the orientation of modernization. The organs there must be streamlined and highly efficient. There should not be too many members in their leadership groups, and limits should be set regarding the numbers and age of their leading cadres, who should also have a relatively high cultural level.

The forum held: Further implementing the special policies and flexible measures and running the special economic zones well is the business of the whole province. All areas and departments must be concerned for this work. All work must conform to this endeavor. All levels of the province must take positive action, get their brains working, come up with schemes and methods, and study specific measures for implementing them in their own areas and units in connection with reality.

LABOR AND WAGES

NEW WAGE SCALE, BENEFITS FOR GUANGZHOU SANITATION WORKERS

Guangzhou GUANGZHOU RIBAO in Chinese 7 Jul 81 p 1

[Article by Yu Hua [3768 5478]: "Improvement in Environmental Sanitation Workers Wages and Welfare Benefits; Municipal Revolutionary Committee Approves Increases in Wages for about 6,000 Environmental Sanitation Workers Beginning from January This Year; Monthly Per Capital Increases To Average More Than 8 Yuan Per Month; Simultaneous Institution of Environmental Sanitation Subsidies"]

[Text] The Municipal Revolutionary Committee today approved improvements in sanitation worker wages and welfare benefits. This will mean an average 8 yuan per month more for the city's more than 6,000 environmental workers. Environmental sanitation subsidies will be instituted simultaneously. These measures are to take effect from 1 January 1981.

The cleanup workers, nightsoil collectors, and ash and garbage collectors, who constitute the environmental sanitation workers of Guangzhou, work with great intensity, frequently laboring day and night. For years their wages have tended to be low. Not long ago, the Municipal Revolutionary Committee undertook a study of the question of improvement in environmental workers' wages and welfare benefits. A leading comrade in charge at the Municipal Revolutionary Committee said, "All departments concerned should urgently implement gradual increases in the political and economic benefits of environmental sanitation workers." All year long, municipal departments concerned have repeatedly investigated and studied this problem to formulate a specific plan. Today the Municipal Revolutionary Committee formally approved its implementation. The four provisions of this plan are as follows:

1. Prevailing wage standards for environmental sanitation cleanup workers under the system of ownership by all the people, nightsoil collectors, street sweepers, and ash and garbage collectors in all districts should gradually make a transition to the wage standards applying to construction workers. The prevailing grade 4 wages paid cleanup workers under the system of ownership by all the people, and paid nightsoil collectors and street coal ash and garbage collections under the system of ownership by the collective should be made into the grade 4 wages paid construction workers. The prevailing grade 5 environmental sanitation cleanup workers, nightsoil collectors, street sweepers, coal ash and garbage collectors should be paid at the 4.5 scale for construction workers. Grade 6 environmental sanitation cleanup workers and nightsoil collectors should be paid at the grade 5

construction worker rate. Environmental sanitation cleanup workers at grade 7 should be paid at grade 5.5 construction worker rate. Grade 4 and grade 5 street cleanup workers should be paid at the grade 3.5 and grade 4 construction worker rates respectively. After being blanketed into the construction worker wage scale, existing supplemental wages will no longer by paid.

2. Benefits for those engaged in labor requiring strenuous physical exertion, as follows: All new workers will have grades assigned in accordance with wage standards for construction workers, and will be paid at the grade 1 level during the first 6 months on the job. Following completion of a year on the job, they will be paid wages at the grade 2 level. After 2 years on the job, and provided they have performed competently, they will receive grade 3 wages.

3. The proportion of award money that may be collected by environmental sanitation workers under the system of ownership by all the people will be increased from the existing 10 percent of wages to 12 percent of wages. So long as it does not exceed 12 percent of total wages, amount of award money paid to nightsoil collector and street environmental sanitations crews in all districts may be decided on the basis of individual income.

4. Cancellation of prevailing health subsidies and institution of environmental sanitation subsidies. Depending on the type of work done, this is to be paid at a rate of 0.20, 0.30, 0.40, 0.50, and 0.60 yuan per person per day.

PROBLEMS OF ENTERPRISE OPERATIONS DISCUSSED

HK120144 Beijing JINGJI YANJIU [ECONOMIC RESEARCH] in Chinese No 6, 20 Jun 81 pp 51-56

[Article by Li Yingzhang [2621 3602 4545] of the Enterprise Management Department of the First Ministry of Machine Building: "A Tentative Discussion on Forecasting and Formulating Policy in Enterprise Operation"]

[Text] The problem of enterprise operation is a very important problem in modern economic management work. It is also a new subject urgently awaiting study and solution with respect to our current readjustment and reform by the various enterprises and their management departments. Good performance in business forecasting and formulating policy is an important part of the modernization of enterprise management.

I

In order to study forecasting and policymaking of enterprise operations, first of all we must understand what enterprise operations are. In terms of general concept, management means the following behavior on the part of the enterprises in their economic activities for the production of physical output: the development of scientific forecasting, the selection of product orientation, the formulation of development plans, the undertaking of product development, the organization and arrangement of production, and provision of good sales service for the purpose of attaining business targets, and this process repeats itself in recurring cycles. Capitalist enterprises pay much attention to operation in their production activities, because the capitalist commodity economy is there, the law of value and competition are playing the role of regulation and stimulation with respect to production, and with the constant progress of science and technology, and diverse changes of market demand, good enterprise management and administration, correct forecasting and formulation of policy play the deciding role with respect to the existence and development of capitalist enterprises and constitute a problem of life or death with respect to the enterprises. If an enterprise makes correct forecasting and decisions, it will be able to develop and grow amid competition. Otherwise, it will close down and become bankrupt. To cite a case as an example, in the United States, there is a well-known corporation, the Chrysler Automobile Corporation, which was struck by a disastrous slump in sales, and was forced to plead for government rescue loans to avoid bankruptcy, because in policymaking it failed to take into consideration the energy crisis, and organized production on the single basis of market preference for large and luxurious cars. In contrast to this, two other U.S. competitors, General Motors, and the Ford Motor Company, developed fuel saving compact cars which had small sales at that time. As a result, the latter two auto companies were benefited with progress. For this reason, invariably capitalist enterprises regard operation and policymaking as matters of paramount importance, for they want to win in competition and reap more profit at less expense. In recent years especially, in operation and policymaking the capitalist enterprises have extensively made use of mathematics, sociology, psychology, computer science, and so on. In consequence, a comprehensive management technology has been developed.

This is how capitalist enterprises are. Is it also necessary for socialist enterprises to pay attention to operation and to do well in forecasting and policy making? For many years, this question has been unclear to us and has been neglected. In our enterprises, attention was only paid to management and never to operation in the past. One important reason for this is that the management system of enterprises was only an appendage of administrative organs in the context of the control system, they were deprived of the autonomous power in operation, management and policymaking which they should have had in their capacity of relatively independent commodity producers. This has led to backwardness in management and administration poor economic efficiency. Looking at the panorama of the economic development of our country, it is precisely due to the lack of understanding of the concept of operation and the absence of scientific forecasting and policymaking on the part of government management departments as well as enterprises that economic errors have been made and can be found everywhere. For example, the duplicated plant locations and blind development of industrial enterprises are quite serious. Although this has much to do with the management system of lines of command and compartmentalization which gave rise to independent spheres of control and the situation of each going its own way, this is also an outcome of the fact that enterprises did not pay attention to operation, forecasting and policymaking, nor did they take into consideration operations efficiency. In the past 2 years, the number of industrial enterprises in our country has been increased by almost 10,000, most of which are redundantly constructed small plants. Again this is a misunderstanding of market demand on the part of many of the enterprises, which caused production to be [word indistinct] from sales, giving rise to new idle funds and waste. Last year, overstocking of electrical and mechanical products was still on the rise, circulation funds tied up in industrial products in the country as a whole amounted to tens of billions of yuan, and the funds are prevented from playing their proper role. All this demonstrates that in a socialist economy, forecasting operations and policymaking of the enterprises are important all the same. It is a requirement of objective economic law to select the practicable business program on the part of the enterprises by means of forecast operations and policymaking in order to gain better economic results with less social labor input, and to improve the operational efficiency of enterprises.

At present, our national economy is in the stage of further readjustment. During the readjustment period, good performance in business forecasting and policymaking by enterprises is of great significance. The reason for this is that by means of forecasting and policymaking the enterprises can improve their service orientation and product makeup to satisfy the needs of society. For the case of individual departments of individual enterprises in particular, by means of business forecasting, appropriate decisions can be made in respect to closing, suspending, merging and shifting for those enterprises that turn out substandard products of poor marketability and quality and thereby suffer business losses for a long time in order to enhance economic efficiency and to facilitate the progress of readjustment.

II

How can a good performance be accomplished in business forecasting and policymaking by enterprises? This question is of much concern to the management personnel of the enteprises. As of now, many enterprises, especially the machine building enterprises, have sent many of their staff, some including their factory directors and party secretaries, out of town to scout for production contracts and for sales. Under the present situation of a shortage of production tasks, this is quite necessary. However, it should be said that this is not an effective way to get a solution to this problem. Sending out personnel to promote sales in itself is not an essential aspect of enterprise operations. To grasp the core of business management, it is necessary to link it with obtaining market information, market investigation, proper forecasting and policymaking, and the promotion and sales of products.

(1) Market investigation. This is the basis for making forecasts. Through investigation, large amounts of numerical data and other information about production and demand are acquired and accumulated, and this provides a reliable and true basis for scientific forecasting and policymaking. However, market investigation itself is not forecasting, nor policymaking. Some enterprises identify paying visits to customers and market surveys with forecasting. Such an identification lacks precision. Investigation and forecasting are related, but they are not identical. Investigation means the acquirement of data, while forecasting requires scientific methods for induction, arrangement of data, measurement, and calculation. These are precisely the problems awaiting solution in respect to undertaking operations. As to how to carry out proper market investigation, in view of the present experiences of some enterprises, the following are the main points:

1. Market investigation should take the product in question as the center of all considerations and the customers as the targets of action in order to ascertain the makeup of customers using this product, and to find out in what economic sectors, industries, regions, entities and by which individuals such products are being used. In the study of the application of the product, active measures should be taken to expand the area of application of the product in order to look into the possibility of introducing the product to new sectors, and new industries as well as the prospect of establishing it on the international market. All this is for the purpose of opening up and developing new markets.

2. Investigation is to be conducted into different categories of products. In terms of the characteristics of mechanical products, generally speaking, they can be divided into two broad categories, the large-scale specialized equipment

(for example, metallurgical equipment and electricity generating equipment) and general purpose equipment (for example, the general purpose lathe and bearing generator). Another division is made for high-grade, precision, and advanced products as one group vis-a-vis ordinary products. For all the different products, detailed investigations should be made in regard to their social demand and market potential. We must acquaint ourselves with the pattern of production and sales, how much last year, how much this year and how much next year. It is only if there is a large market potential that there will be a bright prospect for the future development of the product. While investigating the market potential, study should be made at the same time of the purchasing power of the customers. It is the purchasing power of the customers which determines the volume of sales. After establishing the potential sales volume, further investigation is necessary to find out the market shares of the respective producer plants. With all these investigations properly carried out, then reliable data for forecasting are available.

3. Methodology should be emphasized in making market investigation. In terms of form of investigation, there are two kinds: the direct method and the indirect. The direct method comprises the following: sending out investigation teams or inviting interviewees, visiting customers, holding sales exhibitions, having direct contacts with customers in order to have a good understanding of the past as well as the present, to collect information, and to acquire data. By direct investigation, information can be obtained concerning the requirements of the customers in respect to the product, giving a truer and more reliable picture. Indirect investigation is made by correspondence, questionaires, and by collecting information from the press, advertisements, and so on. Both these methods, the direct and the indirect, can be taken simultaneously so that more information can be collected. With reference to the extent of the investigation, distinctions should be made in accordance with the different categories of products. In the case of large-scale specialized equipment for only a few customers, produced individually or in small batches, investigation can be made case by case in terms of the equipment and the customer, and a separate filing card should be prepared and kept. As for products of general use in large quantities and with broad market applications, the typical pattern or random sampling method should be used for investigation to achieve simplicity and good results. The enterprises should keep up their market investigations unintermittently and systematically so that comparatively complete data may be collected to provide a reliable basis for forecasting and policymaking.

(2) Develop forecasting. By forecasting, we mean carrying on scientific analysis on the basis of market investigation and study, and finding out about development and prospective trends. As far as an industrial enterprise is concerned, the purpose of forecasting is to study the economic rationality of operating and developing the production of the enterprise and to provide a basis for policymaking. Therefore, the forecasting of an enterprise involves the development of products, which include the old products being produced at present and the new products of the immediate future. Market investigation provides the possibility for production to be undertaken by the enterprise. However, in the study of the production of these two kinds of product, attention must be paid to two problems, the life span of the product and its economic limitations, and due forecasts should be made of the two.

As the life cycle of the product implies, the use value of the product undergoes changes with the passing of time. In analyzing any product, it is not difficult for us to find out the variations of its life. Generally speaking, the following stages are undergone: the initiation stage (upon completion of trial production, the product is introduced to the market, and the volume of production is relatively small), the stage of development (the product is accepted by the customers, production is undertaken in large batches, and volume of production rises), stage of maturity (production reaches a peak, market demand for the product approaches stability and saturation point), stage of decline (as new technology and products appear on the market, demand for the product declines), the stage of replacement (the acceptance of the new product and the elimination of the old) and so on. The above stages can be plotted to make a life cycle curve. The job of forecasting of the enterprise is to get a good grip of the life cycle of the product, and to enable proper planning of the four categories of products: (1) planning for the formal undertaking of production; (2) planning for trial production; (3) planning of products in the process of study and design; (4) research work in connection with the application of newly developed technology. This enables the enterprise to have a reserve of products in terms of technological variations, and to practice continuous renovation of its products to meet the needs of the developing social production technology. Take the mechanical products of our country for example, of the present product varieties which number several tens of thousand, 70 percent belong to varieties of the 1950's (not to mention those of the 1940's which number quite a few). Many of these varieties are still in short supply at present. At first glance, they seem to be in the stage of development or maturity. However, after a careful study of their properties and performance, their technological backwardness is bound to be discovered: excessive consumption of energy, low production efficiency, poor quality and precision, insufficient mechanization and automation, and so on. Some of these products should have been classified in the category of decline or replacement long ago. This requires us to change the models and bring in new products. Obviously, in making a judgment on the life cycle of a product, the correct answer can only be attained by taking stock of the developing technology, and taking into consideration the market sales volume alone certainly does not suffice.

In the process of forecasting production, another factor to be taken into consideration is the problem of economic limitations, or the study of effects on value in the development of the product. Any product of an enterprise has its point of profit and point of loss. The purpose of producing in respect to an enterprise is to make profit while satisfying the needs of society. Therefore, production of any product requires compensation in terms of value so that the earnings from production offset consumption (the variable expenses and the invariable expenses). Profit is made, when earnings exceed consumption. Conversely, losses are incurred. This is the critical point of profit and loss of a product. With the increase of production, profit for the product will be increased, so will the profits of the enterprise. When production is increased to a certain maximum level, a turning point will be reached. At this point, the enterprise must improve its conditions, make more investments, expand its production capacity, consequently greatly enlarging its invariable expenses with the result that profits may be reduced, or perhaps may come to nil, depending on the future prospect of sales on the market.

These limitations are called economic limitations of the product, also known generally as the economical production volume, indicating the limit of production that yields the best economic results for certain products under the present conditions. The management personnel are to make selections within the range of points of profit and loss, and economic limitations. The economic limitations relate not only to production volume, but also to price, cost, and so on. When the management personnel make a forecast for product development, correct evaluation can be made only by taking into account the economic limitations and the life cycle of the product.

Making forecasts involves scientific methodology. Various methods are found abroad, which can be generally divided into two models, the qualitative model and the quantitative model. The qualitative forecast depends on surveys made by specialists, on subjective judgments, and mutually effective analyses, while the quantitative model most generally adopts the method of time series, moving averages, and the correlative linear retrogression. To undertake such forecasts, historical data are indispensable. As the current condition of our present enterprises indicates, it is difficult to make forecasts in terms of pure mathematical approaches. However, in order to adapt to the changes in economic management, certain machine building enterprises have adopted some simple forecasting methods and have achieved some good results. For example, in the field of qualitative forecasting, the method of economic trend analysis has been used to study the quantative changes of market demand for products brought about by the implementation of the eight-character guideline of readjusting, reforming, rectifying and improving: with the reduction of investment in heavy industry, investment in agriculture, light industry, commerce and the service trades has relatively increased; with a big reduction in demand for machines by capital construction, such demands arising from tapping potential, renovating and restructuring have been on the rise; with the reduction of tasks for large precision equipment, there have been more tasks for general products; with less state-planned tasks, there have been more private market-oriented tasks, and so on. This is the basis for readjusting the service targets of the enterprises and developing products with good marketability. In quantitative forecasting, the correlation forecasting method has been adopted. Investigation is made in respect to the internal relations of demand to ascertain the correlation coefficient. For example, to raise coal production by 200,000 tons, a coal mine elevator no smaller than 2 meters must be installed; to increase steel production by 1 million tons, 45,000 tons of mining equipment must be added; 1.8 units of vertical cutting automatic lathes and other supplementary equipment are needed to increase production of wrist watches by 10,000; 7,500 electric meters are needed for every 10,000 kilowatts of electricity generation equipment, and so on. In the case of the study of forecasting means of subsistence, the social purchasing power must be analyzed, and typical-case investigation must be made to find out the correlation coefficient. For example, the Beijing survey showed that four cameras were bought for every 100 staff and workers; and 10 percent of all households in the cities of the country as a whole have electric fans. From this data it was concluded that 74,000 cameras and 2 million electric fans are needed in the country as a whole, and so on. With the data concerning national needs, the producer plants can estimate their own sales volume by virtue of their share of the national market. It must be pointed out that any numerical value produced by forecasting is subject to errors, and deviation must be allowed. The necessary revision must be made according to the concrete conditions, when business policy of the enterprise is made. Furthermore, just like the market surveys, no constant forecasting can be found, but corrections must constantly be made according to market information.

(3) Business policy making. Good policymaking for business operation is the crucial question in enterprise competition and development. In a broad sense, it can be said that business management of an enterprise is the process of policymaking, that is, making scientific forecasts on the basis of market surveys in order to produce countermeasures and work out the necessary program. The following steps are included in the process of formulating policies: 1. presentation of the problem and setting the aim; 2. making forecasts and drawing up programs; 3. analyzing and evaluating the technical economic results; 4. selection of the appropriate program; 5. formulating the action program; 6. examination of the implementation of the plan. Here, we find that forecasting is the promise and policymaking the key link. By patterns, there are two kinds of policymaking: the business management (strategic) policymaking which involves the development orientation of the enterprise, the product varieties, scale of production, the making of investments, and the administrative (technical) policymaking, or measures to be taken for the daily control of operations during the process of implementing the program in order to bring about the aims set by the enterprise. Generally speaking, most of the strategic business policymaking is without sequence. That is to say, it is subject to the influences of variable factors which are not quite predictable at present. For example, the variations of market demand, the supply of raw materials and parts made by cooperative parties, the rise and fall of prices, innovation of production techniques, the domestic and foreign competition and other factors influence the decisionmaking of enterprises. Therefore, it is impossible to have a fixed standard solution subject to no variation. Here, much depends on the knowledge, experience and command of information of the manager as well as his ability to judge, his willingness to take responsibility and his courage to take risks. During the process of policymaking, use should be made of the decision pedigree (programs related to the decision are to be shown by pictures and charts in the pattern of a trunk and branches like those of a tree) so that from the programs the most practical and suitable ones can be selected in order to accomplish the aims of the enterprise (not the most superior program, as superiority is only relative). This is one lesson which all senior executives must learn in business operation. In contrast, the technical management decisions being implemented mostly follow definite sequences, with well defined objectives, less uncertain factors, definite programs, and clear numerical data. In such cases, calculation can be made by operational research. Falling into this category are examples such as: rational arrangement of production tasks, the correct size of production batches, selection of efficient working technology, adjustment of labor force to improve the man-hour productivity, shortening of the production cycle, and so on. All these are the tasks of middle-level executives of the enterprises.

Usually, the collective form should be taken, when business decisions are made for the enterprise, as problems involved in making such decisions are comparatively numerous, especially those for business operation which are more complex and more liable to errors, and the collective decisionmaking which pools the wisdom of many people and relies on group study is better than that made by individuals. There are two kinds of collective decisionmaking: for one kind, people are called to the meeting when a decision needs to be made; the decision is reached collectively, or by ballot. For the other, discussions and consultation with experts are held before making the decision, which is left to the final discretion of the chief executive. The trend of business decisionmaking abroad shows the development from individual decisionmaking to collective decisionmaking through a council of advisors. The advantages of this are more information and wholehearted execution of the program after the decision is made. Here, we should take notice of the fact that when business decisions are taken by the enterprise, very often due to the influence of variations of external factors, the decision may become an error, as the accomplishment of its ends may be impaired. Therefore, contingent remedial programs must be drawn up when business policy is made so that remedial measures may be taken when sudden changes occur in order to guard the enterprise against business losses.

Currently, some attempts have been made at business decisionmaking by certain machine building enterprises. The methods are quite simple, but the results have been good. For example, the Ningjiang Machine Tool Factory of Sichuan Province is a producer of precision instrument making machine tools for heavy industry, the military industry and light industry. In the past, its products were in excessive supply, and annual sales were less than 500 to 600 machine tools. In 1979, the factory started making market surveys, forecasts, and business decisions, and the situation has turned for the better. Having analyzed the changes in our national economy, they came to the understanding that (1) heavy industry would be cut down, the market for light industry would be expanded henceforth, several billion yuan of state loans had been granted to light industry, and demand for precision instrument machine tools would be on the rise; (2) the production of watches would be on the rise, as employment would be increased by several million annually, therefore watches would be in demand, especially those for women, hence growth of demand for machine tools for making ladies' watches; (3) equipment of the watchmaking industry would need renovation and transformation; (4) the quality of their products had been comparable to that of Japanese watches, hence the possibility of sales on the international market. By correlation, they have made forecasts and estimates of the demand for the machine tools they produce. First, in respect to the growth of demand for their machine tools due to the increase of production of watches, they have made the assumption that by 1985, 30 million watches will be produced. This means that to reach this figure an annual capacity of 2 million watches must be added each year, and for every extra 10,000 watches, 1.8 machine tools will be needed. Then the annual total figure will come to 360 machine tools. Second, concerning the demand for machine tools due to renewal of equipment, they make the assumption that the replacement rate is 5 percent of the present total of 6,000 precision instrument machine tools owned by the country's watchmaking industry, which amounts to a requirement of 300. The sum of the above two items comes to 660. The Ningjiang Machine Tool Factory's share of the market being 80 percent, the figure for the Ningjiang Machine Tool Factory comes to 500. This is what is needed for the production of watches. Third, concerning the demand of other industries, according to the historical data of the Ningjiang factory, the watch industry accounts for 40 percent of its total sales, and 60 percent is taken up by other industries. This means that 700-odd machine tools are needed by other industries. Fourth, in respect to export needs, the figure for the past years has been 200 to 300. The total demand of the above four items comes to 1,400 to 1,500 machine tools. Accordingly, the Ningjiang Machine Tool Factory has decided to produce 1,400 to 1,500 machine tools annually in the coming few years in keeping with the market situation in our own country as well as abroad, and in accordance with the variety, quality and price of its products, and its capability to compete in terms of its technical services and capabilities. In addition to this, the factory has also decided to adjust its product range and increase its capacity to produce more marketable products in the light of the aims of the policy. In 1980, the factory made arrangements to produce 850 machine tools, which fell short of the customers' demand. This year, arrangements have been made to produce 1,000 machine tools, which again falls short of demand. At present, some contracts have been signed for 1982. Facts show us that the forecasts and decisions made by the Ningjiang Machine Tool Factory are well grounded.

III

Step by step, many of the management personnel of our enterprises and those of our economic administrative departments are paying more attention to the problem of business forecasting and policy-making of the enterprises. This is a new beginning of business management of our enterprises for the past 30 years. Due to the fact that we did not pay much attention to business management in the past, our demand for good forecasts and decisions on the part of the enterprises will give rise to many difficulties. Certain conditions need to be created, but the following are most urgently needed:

1. The government organs in charge of economic affairs must set up consultation and service departments in regard to forecasting and decisionmaking information to provide technical and economic information, and market demands, both in our own country and abroad. It is very difficult for the enterprises to get such information by themselves. For a single enterprise, it is only possible to know the local conditions. Under the conditions of regulation by market mechanism and competition among the enterprises, a large amount of economic information, including the situation of supply and demand is needed to make correct decisions on the part of the enterprises. Without such a prerequisite, a situation similar to the recent one may possibly reoccur with everybody rushing to produce electric meters, electric fans and other "hot property." As shown by statistics, there are nearly 2,000 enterprises producing electric fans, and those that specialize in producing electric meters have increased from 29 to more than 200. Under such conditions, blind production can hardly be avoided. This may very well exert unfavorable influence on our economic readjustment. Consequently, it is absolutely necessary for the government organs in charge of economic affairs to set up information centers, to provide good consultation, to circulate the necessary information, and to help the enterprises do well in forecasting and decisionmaking.

2. In the enterprises (especially those of medium and large size) internal structures in charge of management policy must be set up and be provided with the necessary technicians and managing cadres. Steps must be taken to enable them to learn how to make market surveys and to do well in business forecasts and decisionmaking. As for the senior executives, such as managers and factory directors, they must be provided with better training programs with emphasis on enhancing their capability to run the enterprise and to make decisions as well as increasing their business knowhow and improving their quality.

3. Economic legislation must be enacted. The nature, position, rights, responsibilities, and benefits of the enterprises must be clearly stipulated. Policymaking of the enterprises must be commensurate with their authority. The nature of authority prescribes the nature of policies made, and the scope of authority prescribes the scope of policies made. This provides the enterprises with legal insurance when they make their business decisions. In the meantime, the enterprises must also carry on their business dealings within the scope stipulated by economic laws.

4. The state must have a stable long-term economic and technological development policy as well as long-term development plans with well defined and specific development targets, speed, proportions, economic set-up, and so on, in order to give guidance to the business operation of the enterprises, to integrate the state and enterprise policymaking as well as to combine macroeconomics and microeconomics, and all in all, to enable the national economy to develop more harmoniously. For the present readjustment period, a readjustment plan is also needed. This will facilitate the government organs in charge of economic affairs and all the production enterprises in carrying out the task of economic readjustment more satisfactorily through forecasting and business decisionmaking.

DISCUSSION ON REFORMING ENTERPRISE LEADERSHIP

HK120800 Beijing JINGJI GUANLI [ECONOMIC MANAGEMENT] in Chinese No 6, 15 Jun 81 pp 59-63

[Article by the group for investigation and research on reforms of the system of leadership over the enterprises, under the Shenyang Committee of the CCP: "Reforms in the Present System of Leadership Over the Enterprises Can Help Improve and Strengthen Party Leadership"--slantlines denote boldface type]

[Text] Will reforms of the present system of leadership over the enterprises and also division of labor between party organs and administrative bodies be able to help improve and strengthen party leadership, or will they weaken and lead to the abolition of party leadership? This is a very acute issue facing the experimental units. If this issue is not resolved, our experimentation will not advance with big strides. This year, with our attention focused on this issue, we have convened theoretical seminars, organized study classes for cadres and delivered lectures to the masses. Through such means we have repeatedly studied and discussed, and have preliminarily unified our understanding of, the following three questions: First, what should we correctly understand about leadership of the party committee over the enterprise? Second, are there shortcomings in the present system whereby the factory director is in charge of the enterprise under the leadership of the party committee, should the present system be reformed, and how should it be reformed? Third, how can we work to improve and strengthen party leadership when the relevant reforms have been carried out? In the ensuing paragraphs we will discuss our views on these three question.

I. What Should We Correctly Understand About Leadership of the Party Committee Over the Enterprise

Some comrades have been worried about the possibility that reforms in the system of leadership over the enterprises may weaken and lead to the abolition of party leadership. An important cause of their worry has been the disruption and sabotage by Lin Biao and the "gang of four," coupled with the influences of forces of habit which have prevailed for many years. Their understanding of what constitutes leadership of the party committee over the enterprise has been muddled. Now, when the problems concerning their understanding have been solved, they feel at ease instead of worried, and they actively support the reforms instead of showing disagreement. We have mainly resolved the following three issues.

/1. The leadership of the party committee over the enterprise should mean ideological and political leadership, instead of direct command by the party committee over everything./ Some comrades said that the party should exercise leadership in everything. The enterprise must therefore subordinate itself to the direction by the party committee in everything. If the reforms are carried out, so that the party committee will no longer exercise direct command over the factory director and the staff and workers' congress, then is it not obvious that party leadership is weakened? During the discussions, it has been generally believed that it is incorrect to understand the leadership of the party committee over the enterprise as the direct command of the party committee over everything, with the party committee simply having the say. Party leadership should mainly mean political leadership, and leadership over the line, principles and policies. The party committee of the enterprise should mainly insure the implementation of the party's line, principles and policies at the enterprise. Therefore, the main task of the party committee of the enterprise is to spread propaganda among and provide education to all party members and workers on the party's line, principles and policies, to put forward measures of implementation in the light of the circumstances of the enterprise, to turn the implementation of such measures into the conscious action of the whole staff through painstaking propaganda, ideological work and organization work, and thus to insure that the enterprise will adhere to the socialist orientation, and to insure that the fulfillment of the production plans and various tasks will help continually improve the workers' livelihood on the basis of a continuous increase of accumulation on behalf of the state. In view of the party committee's tasks, it should exercise leadership mainly by bringing the role of organizations at various levels and also the exemplary vanguard role of the communists into play, and by carrying out ideological and political work, instead of by relying on administrative decrees.

/2. The fact that the party committee of the enterprise should exercise unified leadership over it does not imply that all powers related to the running of the enterprise should be vested in the party committee./ According to some comrades, the party committee will have high prestige only if it has power, and it will be able to exercise leadership and people will follow its instructions only if it has high prestige. At present, even though in matters related to the party, administration, finance and cultural affairs, the party committee is in control of powers to run the enterprise, its prestige is not high and its direction is not very effective. If the reforms are carried out, and the decisionmaking power over major matters concerning the enterprise is handed over to the staff and workers' congress, with the power to direct production handed over to the factory director, then the party committee will not have real power, and will it not be in vain to talk about strengthening party leadership? Such a view is also incorrect. Through discussion, it has generally been understood that the need for the party committee to exercise unified leadership implies that the whole enterprise must be unified in ideology and line. The factory director, the staff and workers' congress, the trade union and the communist youth league must be led by the party committee politically. They must rally round the party and work according to the party's line, principles and policies. Politically, each of them must not do things in its or his own way. However, we must definitely not interpret unified political leadership as vesting all powers in the party committee. We must clearly define the functions and powers of each. Each should have its or his own functions, powers and responsibilities. Each should be assigned the power due to it or him. Each should exercise its or his own powers according to the line, principles and policies set by the party. The vast numbers of staff members and workers are the masters of the enterprises. They should naturally have the right to make decisions on major matters concerning the enterprises, and to exercise their powers in their capacity as masters. The party committees should give assistance and support to the masses of staff members and workers in their assumption of the role of masters, and must not act as masters in place of the staff and workers. In particular, they should not have the power to force the masses to follow their decisions. The factory director must be responsible for production at, and the administration of, his enterprise. He will necessarily be the highest leading cadre of the enterprise in matters of production and administration. Because of his status and responsibilities, he must exercise full powers in directing production and administrative work at the enterprise. The party committee should assist, support and guide him in his work, instead of exercising command in place of him.

/3. To fully bring the leading role of the party committee into play does not mean that we must restrict and weaken the roles of the factory director and mass organizations./ Some comrades said that whatever we may say, when the reforms have been carried out, the factory director will play the leading role, the staff and workers' congress will cease to play the role of a rubber stamp, but the role of the party committee will dwindle, and its order of importance will fall from first place to third. This view, which takes bringing the role of the party committee into play as conflicting with bringing the role of the factory director and mass organizations into play, and which holds that party leadership will be weakened when the roles of the factory director and staff and workers' congress are fully brought into play, is incorrect. Through study and discussion, the majority of comrades have realized that to fully bring the role of the party committee of the enterprise into play means that the party committee must satisfactorily perform the work that it should perform, and it does not imply that it should perform the work which the factory director should perform, thus taking others' administrative affairs into its own hands. In an enterprise, although the tasks of the party committee, the factory director, the staff and workers' congress, the trade union and the communist youth league differ, the goal of these people and organizations, namely to do a good job of running the enterprise, is identical. If these organizations can work according to the party's line, principles and policies, and according to the party committee's intentions in connection with political leadership, then party leadership has been embodied. Therefore, the two things are not mutually exclusive, but promote each other. After the reforms have been carried out, if the staff and workers' congress genuinely exercise their rights as masters after we have put an end to the situation marked by "the party committee making calls, the factory director making reports, the representatives raising hands in compliance, and the trade union acting as a utility man"; if the factory director can independently exercise the power to direct production and can work with greater efficiency after we have put an end to the situation in which the factory director dares not take matters into his own hands and must rely on discussion by the party committee; and if the trade union and the communist youth league can independently carry out their work, actively safeguard the legal rights of the masses, and fully mobilize the enthusiasm of the masses in production; then, party leadership is strengthened instead of being weakened. Why do we say so? Because the staff and workers' congress, the factory director and the mass organizations carry out their work under party leadership and must follow the party's line, principles and policies in formulating their working regulations and establishing various rules, regulations and systems. Therefore, the party committee must work to provide necessary guarantees in various aspects and to create requisite conditions (an important condition is to enable them to independently carry out their work) so that they can bring their own roles into play. This is a specific embodiment of party leadership and also an important and indispensible aspect of the exercise of party leadership.

II. The System Whereby the Factory Director Is in Charge of the Enterprise Under the Leadership of the Party Committee Embodies Shortcomings Which Are Unfavorable to Strengthening Party Leadership

When several muddled views on party leadership have been preliminarily clarified on the plane of theory, some comrades have gotten their thinking straightened out and believe that reforms will not weaken party leadership. However, other comrades have been unable to change their thinking quickly. They have held that although the present system embodies the shortcoming of taking administrative affairs into its own hands by the party committee, anyhow, the present system is favorable to strengthening party leadership, and this is the greatest advantage. If the reforms help overcome this shortcoming, but also weaken party leadership, then it is better not to carry out the reforms. Some comrades have said that if the party committee is thought to have undertaken too many administrative affairs, then it can undertake fewer in the future; and if the staff and workers' congress and the factory director are thought to have little power, then they may be assigned greater power. It will be unnecessary to carry out radical reforms. However, what is the real situation? Are there shortcomings in the present system which are unfavorable to strengthening party leadership? During our experimentation, aside from organizing the cadres and the masses to improve their theoretical knowledge, we also organized forces to investigate the situation of leadership by party committees at the enterprises, so as to answer this question using facts. The results of our investigation have proved that not only is the present system unfavorable to enabling the staff and workers to exercise their powers as masters or enabling the factory director to exercise centralized and unified direction over production, but there are real shortcomings in the present system which are unfavorable to strengthening party leadership. The main shortcomings are as follows.

The present system places the party committee in a supreme position and allows it to undertake everything. Consequently, the party committee "cultivates other people's meadows but lets its own land lie fallow." The system whereby the factory director is in charge of the enterprise under party leadership is in itself a system whereby the party is not separated from administration. It combines the system of leadership by the party committee and the system of administrative leadership into a unified entity. Moreover, because the party committee is bent on exercising leadership over the factory director's administrative work, it is therefore the highest organ of power in the enterprise, and the secretary of the party committee is the top leader of the enterprise. Thus, the party organization is above other organizations, and the secretary of the party committee is above other leading cadres. Because the factory director and deputy factory director work under the leadership of the party committee, they will get what they deem to be important or difficult matters discussed at party committee meetings or approved by the secretary. If the masses wish to voice their opinions or demands, or complaints about matters handled by the administrative leaders, they will want to see the secretary. If they cannot contact him, they will think that they have not brought their problems to the attention of the most important person, and will feel dissatisfied. These things give rise to the categories of consequences.

The first category is that all matters must be discussed and decided upon by the party committee, so that it has become an administrative body. Although the present system stipulates that important matters of the enterprise must be discussed and decided upon by the party committee, there is great flexibility in deciding what important matters are, and it is difficult to make a clear classification in practice. For example, if the whole party grasps birth control, then birth control will be an important matter. The allocation of housing and the readjustment of wages are related to the staff and workers' immediate interests. If these matters are not handled well, the staff and workers' enthusiasm will be affected. These are of course important matters. Environmental protection and industrial safety are also important matters because they are related to the staff and workers' physical and mental health. Therefore, in practice, it is very difficult to distinguish important matters from trivial ones that need not be discussed by the party committee. Very often, all matters, important and trivial, are presented for discussion at party committee meetings. Some people are afraid to offend others or to shoulder responsibilities. They require the party committees to decide on matters on which they should make decisions personally. They take the party committees as "shields for protection against blame." Because all matters must be decided upon by party committees, there have been a deluge of party committee meetings. The party committee of Shenyang Enamelware Factory convened 32 meetings in the third quarter of last year. On the average, a meeting was convened once every 2 or 3 days, if holidays were not taken into account. A total of 157 subjects were discussed, out of which 31, or merely 20 percent of the total, were connected with party work. The rest were related to production or administrative work, and moreover, the majority of them were specific problems within the functions and powers of the administrative departments. The party committee very seldom grasped its own construction or political and ideological work. The party members played their exemplary role poorly, and the staff and workers had numerous ideological problems. In the fourth workshop, three successive meetings for reelecting the general branch of the league had been abortive, because the league members did not like to attend the meetings and less than half of them were present. The workshop branch of the party also did not pay any attention to this matter. Thus, it can be seen that the undertaking of everything by the party committee greatly weakens the work of the party.

Another category of consequence is that because the secretary must take command over everything, he becomes the general head of all affairs and is in charge of everything. Under the present system, the party committee has been established as the supreme organ of power in the enterprise, and the secretary has become the number one man, while the factory director is number two, or even number three or four. Therefore, the secretary must take command over all matters, important or trivial, and every kind of work. He takes command in the birth control committee, patriotic committee, civil disputes mediation committee and so on. He is the group leader of various leading groups by a multitude of names, such as those responsible for assessing wages, promotion, the stocktaking of assets, the auditing of funds, staff and workers' education and so on. Otherwise, it will be considered that the party committee does not pay attention to certain kinds of work, or that party leadership is not exercised. The secretary must also attend meetings convened by higher authorities and departments in charge of various trades. He must also attend and deliver speeches at various kinds of administrative work conferences convened in the factory. Because the secretary takes command and has the say in everything, he is actually above various organizations. Consequently, the phenomenon of "what I say goes" and the "patriarchal system" have inevitably emerged. Party leadership has given way to a single person deciding everything. The party's organizational principle has been radically violated. This situation can be attributed to the personal working styles of the secretaries, but has mainly been caused by the system.

This situation of the party committee discussing everything and the secretary taking command over everything is a general phenomenon among the enterprises on the industrial and communications fronts in Shenyang, though the degree of seriousness varies. If we say that allowing the party committee to wield greater power, to be in charge of a greater number of matters and to have the say in everything is favorable to strengthening party leadership, then it follows that the more numerous the things undertaken by the party committee, the stronger will be the leadership. However, the opposite case is true in reality. The units in which the leading role of the party committee is satisfactorily brought into play and ideological and political work is grasped satisfactorily are those in which the party committees have interfered to a smaller extent in administrative affairs. The same is true of an enterprise. Party leadership is really strengthened not when unified leadership is in practice, but when the party is preliminarily separated from administration.

Will production be affected when the party committee ceases to take production and administrative work into its own hands? Not at all. When the system of direction over production has been strengthened, so that the factory director has begun to exercise his functions and powers, and to pay attention to bringing the role of specialists into play, production has improved, and in particular, economic results have become prominently good. Over the past 3 years, the profits turned over to the state by the Shenyang Smelting Works have increased by 10 million yuan annually, at an average annual rate of 30 percent. In particular, very marked successes have been achieved in the tackling of pollution. Over the past 3 years, 50 environmental protection projects have been accomplished. The recovery of resources from the "three wastes" alone has created a value of 17.29 million yuan for the state.

III. When the Leadership System Has Been Reformed, How Can We Work To Improve and Strengthen Party Leadership

How should we reform the system? If the reforms have been carried out, how should the party committee work so that the improvement and strengthening of party leadership over the enterprises can be insured? These are also problems which we must solve in our experimentation. If they are satisfactorily solved, in the future, the resistance to popularizing a new leadership system will be reduced. Because we still lack relevant experiences, we can only discuss several questions that we have considered preliminarily.

/1. We must clearly understand the role and tasks of the party committee of the enterprise with regard to the system./ When the reforms have been carried out, the party committee of the enterprise will no longer execise direct command over or issue orders concerning production and administrative work, and will no longer have the power to make decisions on or veto the work of the staff and workers' congress. However, the entire enterprise must be subjected to leadership and must have a core which can unify various aspects. This core can only be the party committee of the enterprise. Therefore, when the reforms have been carried out, it must be clearly declared that the party committee is the core of leadership of the enterprise. In the regulations governing the work of the staff and workers' congress and of the factory director, it must be stipulated that politically they must be led by the party committee, and their implementation of the party's line, principles and policies must be supervised by the party committee. Playing the role of the leadership core means that the party committee must rally the system of production and administration, the staff and workers' congress, the trade union, the communist youth league and the whole staff of the enterprise round the party, and must unify the ideology of various organizations and the whole staff on the basis of the party's line, principles and policies, so that their efforts will follow the same orientation and they will vigorously do a good job of running the enterprise with one heart. The party committee must exercise political leadership over the work of various organizations, must coordinate their work, and must resolve the contradictions among them.

We think that the party committee of the enterprise should perform four main tasks when the reforms have been carried out.

1. The party committee should lead the whole staff to become masters and to do a good job of managing the enterprise. As the core of leadership, the party committee of the enterprise should take as the objects of its leadership not only the factory director, the staff and workers' congress, the trade union and the communist youth league, but also the whole staff. Under the present system, the party committee very often stresses exercising control over the factory director and over administrative work, and often neglects mass work and leadership over mass organizations. After the implementation of reforms, the party committee must extend its field of vision, must take the whole staff of the enterprise into consideration, and must lay its emphasis on mass work.

2. The party committee must insure the implementation of the party's line, principles and policies at the enterprise. To achieve this, the party committee must, for one thing, conscientiously study and understand in depth the line set by the party; and for another thing, it must go deep into the realities, carry out investigation and research, and master the actual situation of the enterprise and the tendencies and morale of the masses. By integrating these two categories of work, it will be able to clearly recognize which decisions of the staff and workers' congress or of the factory director are correct, and which of their decisions are incorrect. It must require all party members and appeal to the whole staff to vigorously implement correct decisions. It must insure the implementation of such decisions. It must also criticize incorrect decisions and propose ways of rectification.

3. It must correctly handle relations of material interests among the state, the enterprise and the individual. The party committee must insure that the enterprise is subjected to the guidance of state planning, turns over profits as stipulated, and pays taxes. The enterprise must gradually enhance collective welfare for the staff and workers and raise personal income, on the condition that accumulation for the state is continually increased.

4. The party committee must do a good job of ideological and political work, fully mobilize the enthusiasm of the staff and workers in production, and promote the continued development of production. These constitute a regular and very important task of the party committee of the enterprise. If this task is performed well, the political quality of the contingent of staff and workers can be improved, the relationship between the cadres and the masses can be satisfactorily coordinated, and the staff and workers' enthusiasm in production can be mobilized.

It will not be easy for the party committee to perform these tasks really well. When the reforms have been carried out, the demands on the party committee will be greater, instead of smaller; its burden will become heavier, not lighter.

/2. There must be a relatively great change in the composition of the party committee membership./ Because after the reform, the tasks, contents and objects of the party committee's work will change, the composition of the party committee membership should also change. We envisage that after the reform, it will be sufficient for two or three persons among the factory director and deputy factory directors to become members of the party committee. In particular, it is better for the factory director not to be concurrently the deputy secretary. Thus, the factory director will be able to concentrate his energy to do a good job of grasping production and administrative work. The secretary of the discipline committee, the heads of the propaganda department, organization department and party committee office, as well as the leading cadres of the staff and workers' congress, trade union and communist youth league, who perform political work, may become party committee members. Thus, when studying the party's work, they will all understand the situation and have the right to speak. Ideological and political work will be strengthened, and the party committee of the enterprise will consequently be able to play its role more satisfactorily.

/3. The party committee's methods of work must be changed./ After the reform, the party committee will change over from administrative leadership to ideological and political leadership. The intentions of the party committee will be implemented mainly through ideological and political work and through the party members' vanguard exemplary role. The party committee will be unable to issue orders for the factory director and administrative departments to obey, but may pose demands on party members who are responsible for various functions of administrative leadership. The resolutions of the party committee will have binding force on party members, and the observance of these resolutions will be insured by party discipline. Party members responsible for various administrative duties must also frequently report to the party committee or party branch the conditions of their work and their ideological conditions. They must solicit the opinions of the party committee or the party branch beforehand, and must accept the leadership of party organizations, whenever they make major decisions. Some comrades have said: "What shall we do if party members in charge of administrative duties do not comply with the views of the party committee on major issues?" This will not happen in ordinary circumstances. Even if this happens, the relevant party organization may report this to higher-level party organizations, and then the higher leading bodies will absolutely be able to solve the problem by the method of administrative intervention. Moreover, the party organizations may punish party members who do not fulfill party members' obligations or do not observe discipline, and may even expel them from the party. Therefore, it is unnecessary to worry about party members not respecting the views of the party committee. Especially, after the reform, the party committee will be able to concentrate its efforts on grasping the building of itself, so that this will be less likely to happen. Moreover, although the party committee will not exercise direct leadership over the staff and workers' congress, the former may influence the latter through party members among the representatives of the staff and workers, and insure that the latter makes correct decisions according to its intentions. Prior to or during the convention of the staff and workers' congress, the party committee may group the party members together, put forward its demands on them, clearly state the views of the party committee on the matters on which the staff and workers' congress is to make decisions, and require the party members to influence other representatives according to its demands. At meetings of the party, party members may really voice their personal opinions. However, at the staff and workers' congress, they can only act according to the requirements of the party committee, and must not practice liberalism. Some comrades have said: "Even if the party committee has set demands on the party members, and party members who are also representatives of the staff and workers have also worked vigorously, the decisions made at the staff and workers' congress may still be at variance with the views of the party committee. Then, what shall we do? Under this situation, whom should we listen to?" We say that even if this happens, the party committee will still be unable to alter the resolutions of the staff and workers' congress. On hearing this, some people will say: "Then, how can the political leadership by the party committee be realized?" We can do some analysis, and can discover three types of situations. First, the views of the party committee are correct. However, because it has not worked proficiently, its views have not been accepted by the majority of the masses. If the issue in question does not involve major questions of principle, we will have to wait a certain period of time. Before the masses have the necessary consciousness and appropriate demands, we must not force them to do some desired thing. This is also a principle according to which our party deals with the masses. Second, the views of the party committee are erroneous. If erroneous views are not accepted and are corrected before they are put into practice, is it not desirable? Third, the resolutions of the staff and workers' congress go against the party's line, principles and policies or the stipulations by higher authorities. Then, the party committee will have to persuade the factory director not to implement the resolutions of the congress for the time being, and will have to report this to higher authorities, requesting them to give their ruling.

Of course, after the reform of the system of leadership over the enterprises, the party committee's work will not be limited to the items mentioned above. It will also have to satisfactorily grasp the building of itself, rectify unhealthy tendencies, fully bring the party members' vanguard exemplary role into play, satisfactorily grasp the building of the grassroots organizations and party branch, bring the role of the party branch as a combat bulwark into play, and so on. To sum up, the party committee will have a great deal of work to do and its leadership over the enterprise absolutely can be strengthened. We are confident of doing a good job of experimenting on reforming the system of leadership over the enterprises, and are confident of answering relevant questions by means of practice.

FINANCE, TRADE SECTOR ADOPTION OF RESPONSIBILITY SYSTEM URGED

Taiyuan SHANXI RIBAO in Chinese 12 Jun 81 p 1

[Article by reporters and correspondents: "Finance and Trade Sector Should Learn From the Experiences of Responsibility System in Agriculture as Pointed Out by Comrade Wu Guangtang [1976 0342 3272] in a Report Meeting of Provincial Finance Committee"]

[Text] In the report meeting held by the Provincial Finance Committee in Taiyuan in the morning of 8 June, Comrade Wu Guangtang, vice governor of the province, delivered a report and called on the finance and trade sector throughout the province to follow the example of agriculture in promoting the system of responsibility for business management. Among the participants at the meeting were assistant directors, vice mayors and more than 1,000 leading cadres of the finance and trade sector of Taiyuan.

Comrade Wu Guangtang pointed out: Since the 3d Plenum of the 11th Party Central Committee, the practice of various forms of a responsibility system in the vast countryside has aroused the enthusiasm of the broad masses of cadres and people in production, and has resulted in a rapid agricultural recovery and development. There has also been marked improvement in the peasants' living conditions. Spring plowing and sowing for the current year were completed quickly and efficiently. Some people have said in elation: "Consideration for production [in remuneration] means consideration for morale, because morale is essential to production" and "if production quotas are fixed for households, every household will have a cadre."

In a national industrial and communications conference held by the State Council in Shanghai in April 1981, it was decided that an all-out effort be made to promote the system of responsibility for industrial production. The finance and trade sector throughout the province, particularly the commercial, supply and marketing, and food units should follow the examples of agriculture and industry and actively promote various forms of a responsibility system. If we say that the enforcement of a responsibility system in agriculture marks a strategic decision and a turning point in rural work, then we can say with equal justification that the promotion of a system of responsibility for business management marks a turning point as well as an important reform in the work of finance and trade.

In the past, the practice of "eating out of the same pot" and equalitarianism was quite prevalent in business management on the finance and trade front. In a certain restaurant, there were 5 persons engaged in baking sesame seed cakes, and only 19 jin of flour was used each day. Marx' "Critique of the Gotha Program" contains this line: "The individual producer receives back from society--after the deductions have been made--exactly what he gives to it." According to Marx' concept, how much should be the average daily wages for these five persons after deductions? Probably not very much! Then how can there be any labor efficiency, economic results or social accumulation to speak of! How can there be such a situation? The main cause is that the principle "to each according to his work" was not followed. Consequently, whether an enterprise is managed efficiently or poorly, or whether it makes or loses money has no bearing on the workers' economic benefits, and these workers pay no attention to the result of the enterprise's business operation. A worker's income cannot be increased because of his outstanding work performance; nor can his income be reduced because of his poor performance. Then how can the enthusiasm of the broad masses of workers and staff members be aroused?

Comrade Wu Guangtang continued: Since last year, many finance and trade units in the province, such as the Supply and Marketing System of Anze County, the First Retail Department Store of Yuci Municipality, the Food Service of the Supply and Marketing Cooperative in Linfeng County, the Yangshungou Branch of Weizhuang Supply and Marketing Cooperative in Xiangning County, the Datong Hotel of Datong Municipality, the Yuci County Food Company, the food service of Lingshi and Yuxian Counties, the Food Service Company of Pingding County, and the Textile Department Store of Jishan County, have learned from the experiences of the rural areas and set up various forms of system of responsibility for business management. Their concrete methods can be summarized into six different types: first, responsibility for profits and sharing of surplus profits; second, establishment of work quotas, reward for above-quota work, and wage deduction for failure to fulfill quotas; third, the floating wage system under which regular pay, which is the major portion, is supplemented by a minor portion taken from retained profits; fourth, responsibility for an assigned quota and remuneration according to sale (or production) results; fifth, responsibility for loss beyond the approved limit, and such loss will not be made good, however, any loss within the approved limit will be compensated for, and the compensation fund is at the enterprise's disposal; and sixth, responsibility for a set profit quota with rewards for above-quota profits and punishment for failure to fulfill the quota. These units have in practice shown remarkable results.

We should learn something from these experiences and unswervingly promote the system of responsibility for business management in various forms. Following in old ruts or sticking to the old rules and conventions will not provide any good way out. We must emancipate our minds and carry out bold reforms in the light of each unit's actual conditions. Any of the above six concrete methods can be used. For example, ordinary commercial enterprises can adopt the method of responsibility for a set profit quota and proportionate sharing of above-quota profits, and keep up this method for several years. After fulfilling the profit quota, the enterprise can share the above-quota profits with the state. The proportion of the enterprise's share can vary according to different trades, and this share of profits is entirely at the enterprise's disposal. All enterprises practicing the system of responsibility for profit quota should also adopt the system of rewards which, however, should conform to the state's unified regulations. The collectively owned commercial enterprises can also adopt the year-end bonus system in addition to offering rewards according to regulations.

For enterprises operating at a loss in the implementation of state policies, the system of responsibility for loss beyond the approved limit should be practiced. The enterprise will be held responsible for such loss, but there will be compensation for any loss within the approved limit. Part or all of the compensation funds will be at the disposal of the enterprise.

Small or medium-size enterprises can try out the method of paying taxes rather than handing over profits to the state, provided the state's financial revenue is assured. This means that the state can levy income tax from these enterprises. The portion left over after tax payment can be used as enterprise funds or as rewards or welfare funds.

The enterprise can also practice the system of responsibility among the workers and staff members. Some enterprises can adopt the system of responsibility for profit quota; some can enter into contracts with work groups or even individual workers. Some basic level enterprises have already adopted such systems which are particularly effective for photo studios, barber shops, bath-houses, restaurants, vegetable dealers, and laundry and dyeing, repair and sewing trades. Contracts containing specific stipulations concerning the economic indices, the duty and responsibility and the state policies to be implemented, should be signed by the contracting parties.

The enterprises should practice the piece-work system to the maximum extent, if they are in a position to do so. Those which are paying taxes instead of handing over their profits to the state can use the floating-wage system instead of giving any reward. In collectively owned enterprises, the wages and fringe benefits of the workers and staff members can be the same as, or even more than, those given to the personnel of state-run enterprises of the same trade.

The principle "to each according to his work" should be adhered to in the use of reward funds, and equalitarianism should be positively opposed. Generally, the workers and staff members on the first line of production deserve higher rewards than those working in the administrative departments. The difference of the types of work and in working conditions should also be considered. Therefore, those doing dirty and tedious work, and those working under very poor conditions should be better rewarded in order that the money thus spent can serve the purpose of spurring the advanced elements and arousing the enthusiasm of the workers and staff members.

GUANGDONG REVENUE INCREASED IN FIRST HALF OF 1981

Guangzhou NANFANG RIBAO in Chinese 9 Jul 81 pp 1, 3

[Article by correspondent: "Guangdong Financial Income in First Half of 1981 Increased by More Than 10 Percent Over Same Period of 1980--Remarkable Success of 'Cooking in Separate Kitchens'"]

[Text] By the end of June, Guangdong's revenue was already 53.6 percent of the amount in the annual budget adopted by the Provincial People's Congress, showing an increase of 11.89 percent or 220 million yuan over the same period of 1980. Three municipalities--Guangzhou, Shenzhen and Zhuhai--five prefectures--Foshan, Shantou, Zhanjiang, Huiyang and Shaoguan--and all enterprises under the provincial jurisdiction overfulfilled the plans included in the annual budget.

This is the 1st year of "Cooking in Separate Kitchens," a system of financial management enforced by the provincial authorities among all prefectures, municipalities and counties. Party committees, government bodies and economic departments at all levels have earnestly implemented the Central Committee's policies and the whole set of resolutions of the State Council concerning economic readjustment. They have done a great deal of work, surmounted many difficulties, and achieved marked success. The economic situation throughout the province is excellent. In the first half of 1981, the province's total industrial output value increased by 11 percent over the same period of 1980, including a 16.9 percent increase of light industrial output value. Because of increased production, the market has become brisk while foreign trade and economic cooperation with foreign countries developed rapidly. All these have provided favorable conditions for an increase in revenue.

The provincial authorities have also carried out a vigorous campaign to check on tax evasion and to remind the units concerned of the need to pay taxes. In the first half of 1981, 55.4 percent of the annual plan for industrial and commercial taxation was fulfilled, showing an increase of 14.16 percent over the same period of 1980.

According to information received, the province still has certain problems organizing revenue. The main problem is that some state-run industrial enterprises fail to show satisfactory economic results. There is an increasing number of enterprises operating at a loss, and the total amount of losses is also increasing. Consequently, the profits handed over to the government have declined. The departments concerned have expressed the hope that the leading organs at various levels will adopt strong measures to help these enterprises turn losses into profits in order that increased production will mean increased revenue and the plan for handing over profits to the state can be fulfilled.

SHANXI STRESSES NEED FOR CURRENCY CIRCULATION CONTROL

Taiyuan SHANXI RIBAO in Chinese 8 Jun 81 p 1

[Article by correspondents Wang Yikai [3769 0001 7030] and Liu Feng [0491 6912]: "Strictly Control Currency Issuance and Vigorously Organize Currency Withdrawal--Shanxi Province Held First Conference To Analyze Situation of Currency in Circulation"]

[Text] The first conference held to analyze the situation of currency in circulation ended on 24 May. The participants at the conference pointed out that although the situation of currency circulation in the first 4 months of 1981 in the province was better than expected at the beginning of the year, great efforts on the part of the people's banks at various levels are still required to control the irrational issuance of currency and to organize the withdrawal of currency from circulation, in order that the plans for the control of currency issuance for the first half and the whole of 1981 could be fulfilled.

To insure that currency issuance could be kept within the planned limit for the first half of 1981, the conference urged the banks at various levels to continue the implementation of the readjustment policies and to strengthen their credit control. While controlling irrational currency issuance, these banks were also urged to organize large-scale currency withdrawals. Great efforts should be made to support the industrial sector in increasing the production of consumer goods for daily use, goods with more different designs and varieties, and the production of readily marketable commodities for the urban and rural areas. The production of these goods will provide a stronger material basis for the withdrawal of currency. Support in the form of funds and accounting should also be given to the commercial sector so that it will have more sources of goods. Such economic levers as bank credit and interest rates should be used to reduce stockpiling and to dispose of certain problem goods so that the potentials, now being kept in warehouses, could find their way to the market and thus help in currency withdrawals. Support should also be given to the development of "tertiary industries" so as to expand currency withdrawal with noncommodity means. The network and stations for people's savings deposits should be increased and there should be more personnel with better attitudes toward work, to provide better service. This will absorb more idle funds from the community. Cash control should also be strengthened particularly in the rural areas. The lavish payment of wages, bonuses and welfare allowances should be stopped so as to eliminate all unjustifiable transactions and to reduce cash payments.

HYDROPOWER CONSTRUCTION ACHIEVEMENTS IN 1980 LISTED

Energy Commission Official's Interview

Beijing SHUILI FADIAN [WATER POWER] in Chinese No 4, 12 Apr 81 pp 3-5

[Interview: "Speed Up Hydropower Construction in China by Giving Full Scope to Our Superior Energy Resources--Li Rui [2621 6904], Deputy Director of State Energy Commission and Vice Minister of Electric Power Industry, Answers Questions From our Correspondent"]

[Text] Question: What are the achievements in hydropower construction and production in our country?

Answer: In 1980 we achieved heartening results in hydropower construction by implementing the line of the Third Party Plenum, which marked a turning point after 10 years of turmoil. The main achievements are as follows:

1. New achievements following the general survey of our national hydropower resources during 1977-1980: We discovered a hydropower reserve of 680 million kilowatts, which is approximately 100 million kilowatts above what was discovered following the general survey in the 1980's. The installed capacity of what can be exploited and utilized was 370 million kilowatts, with an annual generation of 1.9 trillion kilowatt-hours. The latest general survey further proved that we have very abundant water resources. This is very encouraging news.

2. New achievements in the construction of hydropower stations: Following the successful damming projects for the Longyangxia Hydropower Station, we completed three more damming projects--for the Gezhouba, Dongjiang and Dahua hydropower stations--in 1980 and early 1981. The Gezhouba Hydropower Station, the first large one on the main channel of the Changjiang River, is being designed and built by the Ministry of Water Conservancy, and the success in damming symbolizes a great step forward in hydropower construction in our country. This was also a prerequisite for the inauguration of power generation and navigation in July 1981. In 1980, the construction of large and medium-size hydropower stations in our country involved a total of 25.59 million cubic meters of earth and stone work and 2.51 million cubic meters of poured concrete.

3. A large hydropower station in the southwest--the Wujiangdu Hydropower Station, which has been formally commissioned--and three medium-size ones, namely the Hunanzhen, Taipingxiao and Chitan stations. The equipment for these three stations

has been completely installed, and their installed capacity reaches 480,000 kilowatts. By the end of 1980, the total installed capacity of our hydropower stations (including large, small and medium-size ones) already exceeded 20 million kilowatts.

4. In 1980, the volume of generated hydropower throughout the country was more than 8 billion kilowatt-hours over that of the previous year, an increase of 16 percent. This is a fairly large increase in hydropower generation in our history, and means a saving of approximately 4.8 million tons of coal. Because of the violation of principles of normal reservoir operation during the 10 years of turmoil, many hydropower stations were for a long time operating at low water levels. After the 2 years of readjustment, starting in 1980 the majority of hydropower stations in the country basically resumed operation at the normal water level. In 1980, our country suffered from flooding in the south and drought in the north; yet, on the whole, it was a year of fairly good harvest. The electric power stations at various levels paid greater attention to their operation, further streamlined the power grid systems, emphasized the need for strict compliance with the orders concerning the control of water levels, and implemented the "Tentative Regulations for the Economic Operation of Hydropower Station Reservoirs" issued by the State Economic Commission. The task of power generation for the whole year was duly carried out at each and every level. Thus, favorable conditions were created for the full utilization of water energy, reduced water consumption and greater power generation.

5. The advance work of hydropower construction has made new progress. The rebuilding of the East China, Central-South and Northwest Survey and Design Institutes, which were wrecked or downgraded during the 10 years of turmoil, also made certain progress, and all the institutes began to concentrate their manpower and material resources on carrying on their work during their reconstruction under crude conditions. In 1980, the hydropower survey and design units directly affiliated to the ministry completed seven planning reports, six damsite selection reports and five preliminary designs. In the same year, 1,126 holes totaling 82,000 meters, were drilled with machinery; 272 holes, totaling 2,600 meters were drilled using indigenous methods; and 12,000 meters of adits and 79,000 meters of troughs were excavated.

Question: What are the plans for hydropower construction in view of the further readjustment of the national economy?

Answer: Despite the state's financial difficulties, full consideration has been given to investments in the electric power industry. This is a fairly clear indication of the central government's strategic policy for energy development. While implementing the central government's readjustment policy and continuing to eliminate the "leftist" influence, we should make conscientious efforts to perform our duty well in the following respects:

1. Strive to manage and operate the existing hydropower stations efficiently. Although the development of hydropower has been slow in the past 30 years for various reasons, our existing hydropower stations still have a total capacity of more than 20 million kilowatts (more than 100 times that of the early post-liberation period). This is quite an achievement, and should serve as a base for the continued progress of our hydropower undertaking. We gained very good results in

the economic operation of hydropower stations last year. Hereafter, we will continue to implement the "Tentative Regulations for the Economic Operation of Hydropower Station Reservoirs." As conditions permit, we will use the best possible form of administration, strengthen the unified control of power grids and the coordination of thermal and hydropower stations, and practice energy conservation to the maximum extent. At the same time, we will pay attention to the maintenance and repair of buildings for hydropower engineering and of the machinery and power equipment, with particular reference to security inspection at large dams and other important buildings. At present the power generating equipment of some hydropower stations is not functioning efficiently. As a result, there have been quite a number of accidents requiring frequent inspections and repairs. This causes a huge loss of energy and the situation should be studied and improved through coordination of our efforts with those of the machinery and power equipment manufacturing departments.

2. Pay close attention to the projects still under construction and be sure that they can safely withstand the seasonal flooding. Altogether there are 22 large and medium-size hydropower stations under construction in 1981, with a total capacity of 10 million kilowatts. There has been some reduction in investments in hydropower construction this year; we must consider the state's difficulties and make the best use of the investments. While insuring that their work is of high quality, all units having enough production tasks should plan for the progress of their work in a rational way and in accordance with established policies in order to fulfill their construction tasks for the current year. Those units not having enough production tasks should try to look for more work on their own at the same time doing a good job of the tasks they have already been assigned by the state. They must try to reduce losses resulting from work stoppage. All projects should be meticulously completed so that nothing whatsoever is left undone. In this way, the projects will be ready for operation soon after the delivery checks. In dealing with projects under construction, we must conscientiously draw our lessons from the projects in Wujiangdu and Huanglongtan, and work out meticulous plans to combat flooding. The four major projects--Gezhouba, Longyangxia, Dongjiang and Dahua--include the building of cofferdams to check the water flow. We can never afford to be careless in these projects. The task of flood control at the Wujiangdu and Baishan projects is quite arduous. We must take every precautionary measure by planning our work well in advance, strengthen the system of reporting on the flooding, have all flood-control equipment ready, and improve the organization of flood-prevention work by providing more active leadership in order to cope with flooding effectively.

3. Do our advance work well for hydropower construction. One of the obvious problems in our hydropower construction is the poor quality of our advance work. This is the result of the abolition, downgrading and "smashing" of the survey, design and scientific research organs. Although the number of projects to be started was greatly reduced during the period of readjustment, advance work is still of great importance. In addition to carrying out the design work for the present projects, we must also prepare for future developments in the way of planning and design. Investments in the reconstruction of the three design institutes have been reduced. We hope all the workers and staff members of the units concerned will consider the state's difficulties and endeavor to do their work well in respect of both quantity and quality, despite the difficult working condtiions. In the current year, the state has allocated more funds for prospecting for water resources so

as to speed up the advance work. In order that these funds can be fruitfully used, we must strengthen our economic accounting system, enforce strict control, observe the financial and economic disciplines, and oppose waste, extravagance and other unhealthy tendencies.

In the selection of sites during the advance work period, we must change the former method of determining the site before planning and demonstrating its worth, since such a method is contrary to the procedures of capital construction. To insure a high quality of survey and design, we should strengthen our legislation and strictly observe the established standards so that our advance work will have a sound and reliable foundation.

Besides insuring the continued progress of the large and medium-size projects which are still under construction, the arrangements for hydropower survey, design and planning should also take into account some other large and medium-size projects which may be started in the near future. Also, in accordance with the present financial and material resources of the state and the need for electricity in various localities, we should look for some sites in places with favorable conditions for medium-size hydropower projects which require less investment and shorter construction periods, but yield quick returns. We should carry out the survey and design quickly so as to expedite the development of hydropower. It is hoped that all design institutes will work out a comprehensive arrangement for the work of survey and design for the current year and give full play to the enthusiasm and creativity of all the survey and design personnel.

4. Strengthen scientific and technological work. To speed up hydropower construction (including the advance work), lower the construction cost, and improve the quality of work and management, we must further step up our scientific study and experiments and strive to adopt and popularize new techniques. For this reason, we should see to it that the scientific organs for hydropower are adequately staffed and strengthened in order that science and technology can be given full play in survey, design, construction and production.

5. Attach great importance to quality and raise the level of management. We should carry out various basic tasks well, with high quality as our central goal. All units concerned should be well organized, and the various rules and regulations should be established and perfected as required. All units responsible for survey, design, construction and installation should respect science, abide by the rules and regulations, strengthen quality control, and cultivate in the workers and staff members the good workstyle of having a high regard for quality.

In the current year, we should further improve business management, strengthen the systems of quota production and financial and material control, follow the economic laws, be concerned with economic results, and increase our work efficiency. The General Bureau of Hydropower Construction should continue to provide good research classes in enterprise management, which are to be attended by the leadership and backbone elements of its directly affiliated bureaus and institutes.

6. Carry out plans for comprehensive utilization and for relocation of people. Throughout the past 30 years, workers in the hydropower sector have consistently attached great importance to the principle of comprehensive utilization of the

river courses. Because of disruptions from the "left" during the 10 years of turmoil, however, many problems have cropped up in this aspect of our work. In such matters as requisition of land and relocation of people, material supplies, posts and telecommunications, commercial undertakings and so forth, we have had many conflicts with the localities. We have not handled the problems of floating logs and navigation effectively. But a more serious problem has been that of people's relocation. We should make a real effort to solve these problems through consultation with the departments and localities concerned. There is an urgent need to set up rules and regulations, to be approved by the State Council and then relayed to the lower levels, so as to provide proper work guidance.

7. All engineering units should devote more effort to the establishment of rear bases. For 20 or 30 years workers and staff members at the worksites (including the field survey personnel) have worked and lived deep in the mountains and gullies where living conditions are harsh. They have had problems with the education and occupation of their sons and daughters, and with the separation between husbands and wives. These problems cannot be easily solved and have remained for a long time, thus creating instability in varying degrees. They can only be gradually ironed out in accordance with state policy, but the most important point is that good rear bases must be set up so that everyone can strive for the four modernizations with peace of mind.

8. Step up technical training. There is now a scarcity of young people qualified to take over the work of the old-timers in the technical force of hydropower construction. This situation should be quickly remedied. The main force in many survey and design institutes is now largely made up of people in their forties, fifties or sixties. Very few of them are around 30 years of age. It is an urgent task to train the young people in view of the serious problem of aging in the capital construction force. In the current year, we should take full advantage of our abundant manpower during the readjustment period to strengthen our training program for our young workers and young technicians. The old backbone elements should also learn something new in order to help solve the problem of technical renovation. All bureaus and institutes should work out their plans and arrangements for an overall improvement of the technical and professional force.

Question: Recently, SHUILI FADIAN No 2, 1981, carried the report, "The New General Survey and New Achievements of Our Water Resources." Please tell me about the significance of these new achievements to the four modernizations.

Answer: Some 2,700 persons throughout the country participated in the general survey of water resources. This survey lasted more than 3 years, from April 1977 to October 1980. The participating units realistically analyzed and studied more than 3,000 results of general surveys, prospecting, investigations, planning and design for water conservancy and hydropower. They also collected numerous data on hydrology and terrain, carried out repeat surveys or supplementary investigations of more than 1,400 large and small river courses totaling approximately 90,000 kilometers, and took measurements on more than 10,000 large and small river courses. On the basis of this gigantic task, the general survey determined theoretically the amount of our national water resource reserve and for the first time ascertained the water resources available for exploitation in the country. The result of this general survey reflects an in-depth study of our present water resources and is of great value to our country in working out realistic energy policies in the future. Moreover, it provides a criterion for the study of the energy pattern of various localities and the strategic layout for hydropower construction. Since there was no verified data on Taiwan Province, this general national survey did not include this province. We hope the hydropower workers in Taiwan Province will supply the data on Taiwan's water resources so it can be included in our future supplements.

Although many general surveys of our national water resources have been conducted in the past 30 years, this is the first one that has been able to determine and provide statistics on the resources that are available for exploitation. At present, only 40 percent of the resources specified in the general survey have been worked on in earnest, or exploited, the majority of them still await on-the-spot inspection. Hereafter, we should step up our study and investigation of the water resources that are ready for exploitation. Our study should not be confined to technical feasibility alone; more important still, we should also study the economic factors rationally. After study and investigation, we will be able to utilize our water resources economically. This will be the main task for our hydropower workers in their future study and investigation of water resources.

Question: What is the outlook for hydropower development in our country. What do you anticipate will be the hydropower situation in the year 2000?

Answer: Judging by the actual situation of our national energy resources, we can see that for a fairly long time to come we will depend mainly on coal and hydropower for electricity generation. Of course, nuclear power should also be included on our agenda, while the use of other sources, such as geothermal energy, wind power, tidal energy and methane, should also be studied. Water resources and coal are not evenly distributed in our country. Coal is mostly produced in the north and the east, while water resources abound in the south. Therefore, in accordance with the power structure ofour country, thermopower is mainly used in northern and eastern China. (In Zhejiang, Fujian and Jiangxi in eastern China, there are more than 10 million kilowatts of hydropower waiting to be exploited.) In the central-south, there is a combination of both thermal and hydropower. (Hydropower is more plentiful than coal in the central-south.) In the past 30 years, because of the fairly good foundation of our coal industry, the availability of railway and water transport, and the low cost of coal, it was more practical to develop thermopower. Furthermore, we did not consider the development of hydropower from a strategic point of view and we had to confine our activities within the limits of our annual investments. Thus the development of thermopower was faster than that of hydropower. Now, our coal production and capital construction have slowed down, the development in various regions has become more uneven, our railway and water transport facilities are severely strained, and there is hardly any prospect of increased petroleum output in the near future. Therefore, the development of hydropower has to be speeded up as an urgently needed solution to our energy shortage problem. People have realized that the development of hydropower is in line with the strategic policy of national economic development. The leading comrades among the central authorities have repeatedly pointed out the need to develop hydropower, and Comrade [Zhao] Ziyang in particular called it "a measure to promote the welfare of future generations." Therefore, the state should take some special investment measures to solve this long-standing problem. I believe that by following the formulation of this correct policy of the central authorities, there will naturally be great development of the hydropower industry in the future. In 1980, the volume of generated hydropower constituted 19 percent of the total power output, and we envision an increase of this proportion to approximately 30 percent. We must strive to attain this goal. If we have more funds, this plan can be even overfulfilled. I hope that the leadership of various localities and at various levels and in all trades and undertakings throughout the country will show their concern for hydropower construction and pool their resources to speed up the development of hydropower.

Gezhouba Engineering Project

Beijing SHUILI FADIAN [WATER POWER] in Chinese No 4, 12 Apr 81 pp 14-15

[Genearl Surveyof the Gezhouba Hydro Project"]

[Text] The Gezhouba engineering project on the Changjiang River is located approximately 3 kilometers below the Nanjinguan pass outside the three-gorge area, and serves an area of 1 million square kilometers, or 55 percent of the entire drainage area of the river. The damsite is located at that section where the river, after passing the narrow and deep gorges, comes to a broad and shallow basin. The surface of the river abruptly widens from 300 meters in the gorge area to 2,200 meters at the damsite. After passing the gorges, the river flows eastward and then abruptly turns south with its depth greatly reduced. There are two islets--Gezhouba and Xiba--in the middle of the river, dividing it into three channels, known as the main, second and third channels. Because of the rocky projections along the left bank at the Nanjinguan pass, the main current is deflected to the main channel at the right. The river basins in the second and third channels are higher, so water flows over them only during flood seasons. For many years, the average flow of water at the damsite has been 14,300 cubic meters per second, and the average runoff has been 453 billion cubic meters. According to historical records, the most serious flood occurred in 1870, with a flow of 110,000 cubic meters per second. The lowest water level is generally in February with a minimum flow of 2,700 cubic meters per second. For many years, the average amount of silt carried downstream has been 520 million tons each year. The geological structure at the damsite is formed of a combination of conglomerate rocks, siltstones, and clay-siltstones of the Cretaceous system, including some intermediate layers of bury. The rocky layer stretches out toward the left bank and is slightly biased toward downstream at a dip angle of 4-8 degrees. The clay-siltstones are rather brittle, decay easily, and are weak in abrasion resistance. The coefficient of friction between the small dip angle and the soft and weak intermediate layers is small, and this is the controlling factor in the stability and security of the construction structure.

The Gezhouba project mainly consists of the construction of ship locks, powerhouses, a spillway, scouring sluices and other structures for checking the water flow (see diagram).

The various technical units and indexes for this gigantic project are shown in the following table.

Item	Unit	Index
Designed water storage level for reservoir	meter	66
Verified flood water level	"	67
Dam top height	"	70
Axis of dam	"	2,561
Total reservoir capacity	100 million meters^3	15.8
Designed flood flow	meters^3/second	86,000
Verified flood flow	" "	110,000
Construction designed flood flow	" "	66,800
Designed water head for power generation	Meters	18.6
Maximum generating water head	"	27
Guaranteed power generation	10,000 kW	76.8
Installed capacity	"	271.5
Average annual power generation	100 million kWh	141
Concrete work for project	10,000 meters^3	990
Earth and stone work	"	9,000

The navigation facilities provided by the project consist of ship locks and waterways. The highest water head for each ship lock is 27 meters. There are two large ship locks in the third channel: No 2 ship lock on the right with a net chamber width of 34 meters, an effective chamber length of 280, and a depth of 5 meters, allowing the passage of 10,000-ton ships; and No 3 ship lock on the left with a net chamber width of 18 meters and an effective chamber length of 120 meters, allowing the passage of passenger and freight ships on the Hankow-Chongqing run as well as local boats. No 1 ship lock is located on the right side of the main channel and is similar to No ship lock. In the third channel, there are navigation routes totaling 6.4 kilometers both upstream and downstream, and a 1,750-meter anti-silt-deposite dike upstream which controls the main flow of the third channel by slowing down the swift current, keeping it smooth and steady and then directing it sideways to remove the silt. The navigation route upstream is 180 meters wide with a 230-meter entrance, and the one downstream is 120 meters wide with a 150-meter entrance.

[See diagram of Gezhouba Engineering Project next page]

23. Anti-silt-deposit dike.

The powerhouses are of the river basin type, and the powerhouse buildings also serve the purpose of checking the water flow. The first and second powerhouses are located in the second channel and the main channel. The one in the second channel is equipped with two 170,000-kilowatt and five 125,000-kilowatt hydraulic turbines, with an installed capacity of 965,000 kilowatts. The powerhouse on the main channel will be equipped with 14 sets of 125,000-kilowatt hydraulic turbines, with an installed capacity of 1.75 million kilowatts. The total installed capacity of the powerhouses will be 2,715,000 kilowatts. Silt-drainage sumps are built under these buildings, and the anti-silt-deposit dikes outside the buildings help prevent the silt from clogging the hydraulic turbines and wash away the silt deposits from the entrance to the powerhouses.

The spillway is of the flat-bottom type. It is 12 meters wide with the floor at an elevation of 37 meters. This spillway is intended for discharging floodwater and is built according to the contour of the river. It will also serve the purpose of navigation when the main channel is closed during the second stage of the project. Each gate has two doors. The upper one is made of a 12 x 12 meter steel plate and the lower one is arc-shaped, also measuring 12 x 12 meters [as published]. The upper one is operated by a machine installed on the top of the dam, and the lower one is operated by a separate special mechanism. Both doors can be opened or closed in perfect coordination. Since the arc-shaped door has an axial thrust of up to 4,100 tons, an anchor structure of prestressed steel bands is required, (see article, "Prestressing of Gate Mounts for Gezhouba All-Purpose Project" in SHUILI FADIAN No 2, 1981) so that the anchor block and the gate mount will form a single solid entity. Maximum drainage over the apron is 170 meters^3/second/meter, and in view of the weak rocky foundation, selection of the form of stilling basin called for extra care. After testing and verifying with models, it was decided to use a 180-meter stilling pool with a completely sealed drainage apron. Later, a 70-meter concrete section was built as reinforcement together with a vertical concrete seepage interception wall which extends down below the bottom of the erosion ditch downstream. At the bottom of the ditch are also 52 anchor piles of a diameter of 850 millimeters to strengthen the seepage interception wall. At the end of the stilling basin, an 85-meter concrete section was added as a precaution against erosion, and on this section, there are 991 reinforced 2 x 2 meter square blocks used as a means ofminimizing erosion downstream.

The Gezhouba engineering project is being undertaken in two stages in accordance with the topographic features of the damsite, and two different navigation routes have to be used at different stages. The first stage includes the building of cofferdams for the second and third channels, with the water flowing only through the main channel. The second stage calls for the main channel to be closed, and the work completed in the first stage to be in operation, with the water going through the completed gates on the second and third channels. The building of a cofferdam and other structures on the main channel is included in the second-stage work. During the first stage, this engineering project required a total of 6.2 million cubic meters of concrete, more than 60 million cubic meters of earth and stone, and 27,000 tons of metal structure. Work during this stage was heavy and intense. In the peak year, more than 9 million cubic meters of earth and rocks were excavated and more than 5 million cubic meters of rockfill were used. In addition, some 2 million cubic meters of concrete were poured each year, and in the peak year some 22,000 tons of metal structure were used for the gates and the open/close mechanism. The foundation also required a large amount of engineering work. The structure of the buildings is very complex, in view of the many mounts, beams and holes. The frames and other structures used for the powerhouse building were mostly made of materials retrieved at a later stage; the construction procedure is very complicated, requiring a huge amount of reinforcing bars and shaped plates, as well as the use of high-grade cement of complex specifications, a strict temperature control and high-level technology. The apron below the spillway, for instance, is built of No 400-grade cement. There is also a set of double-level water stops requiring huge metal parts of many varieties. For the lower inverse "V" shaped door of No 2 ship lock, for instance, a steel water stop is used, and a single swing door weighs 600 tons; requiring high-level precision for its installation. The stone and earth work proved equally difficult, aside from the need for strength and sturdiness. Removing the brittle intermediate layers necessitated sinking many deep holes, some of them as deep as some 20 meters for the foundation of the spillway, and more than 40 meters deep for the main powerhouse section. Pre-set dynamite had to be used for this purpose. As for work progress, the original schedule called for the closure of the main channel by the end of 1981 so that by 1982 navigation and power generation would begin. After great effort, however, the closure was carried out by the end of 1980. The winding-up of the first stage work is now in progress, and the closure of the main channel was successfully completed on 4 January 1981.

SICHUAN HYDROPOWER DEVELOPMENT PLAN EXAMINED

Beijing SHUILI FADIN [WATER POWER] in Chinese No 4, 12 Apr 81 pp 29-33

[Article by Zhang Derong [1728 1795 2837] and Cai Chengzhong [5591 2110 1813] of the Chengdu Investigation and Design Institute under the Ministry of Electric Power Industry: "Some Problems of Hydropower Planning in Sichuan Province"]

[Text] Sichuan has water resource reserves of more than 150 million kilowatts, which is equivalent to 22 percent of the total national reserves. The province has some 380 rivers, each with a capacity of more than 10,000 kilowatts, and approximately 93 million kilowatts of installed capacity, or 24 percent of the national capacity. It has an annual power generation of 515 billion units, or 27 percent of the national power output. To make full use of Sichuan's water resources as envisaged in the preliminary plan for our national energy resources and electric power, we should develop hydropower on a large scale so that in addition to meeting the need for long-range development of this area, we can also transmit a large amount of electricity to eastern China, the central-south and other areas. Petroleum is now very scarce in Sichuan, while coal and natural gas are far short of our long-range requirements. So there is an urgent need to develop hydropower by adopting various effective measures. Taking into consideration both the whole country and this region, we should carefully work out our river planning and long-range plans for our hydropower construction so that we can develop our superior water resources with the minimum investment and maximum economic benefits. This is now an important task for Sichuan's hydropower development, calling for prompt and decisive action.

For 30 years, since the founding of the people's republic, the units concerned have done a great deal of work for the exploitation of Sichuan's water resources. In hydropower planning, our institute, since its inception in 1956, has carried out many surveys and worked out many plans with varying details in cooperation with the other units on such large rivers as the Minjiang, Jialingjiang, Daduhe, Qingyijiang, Yalongjiang and Jinshajiang, and such small and medium-size rivers as the Yuzixi, Nanyahe, Longhe, Tangjiang, Chishuihe, and so forth, in addition to two large-scale general surveys--one in the 1950's and the other in the last several years. At the same time, we carried out some provincial and regional comprehensive planning. On the basis of planned site selection, we built the Longxihe Cascades and the Dahonghe Hydropower Station in the 1950's; and then by the early 1960's, we built several large and medium-size hydropower stations at Gongju, Yingxiuwan, Yuzixi and Mofanggou. By the end of 1979, the province had a total installed capacity of 1,885,800 kilowatts of hydropower, including an installed capacity of 1,192,300 kilowatts from the large and medium-size hydropower stations affiliated to the institute. The total power generated was 36.4 billion units, or 32.8 percent of the total generation by stations affiliated to the institute. Profits from hydropower totaled 1,891 million yuan, or approximately half of the profits from the entire power grid. The hydropower accumulated funds reached 2.337 billion yuan, or 45.3 percent of the accumulation of the entire power grid. The state invested a total of 1,034,600,000 yuan in eight power stations, including the Changshou Power Station (which includes the four cascades at Longxiha and the Dahonghe Hydropower Station) and the Gongju, Yingxiuwan and Yuzixi power stations. From the time of the linking of the power grids up to the end of 1979, the power generated totaled 3,412,200,000 kilowatt-hours, which yielded accumulated funds of 2.197 billion yuan. The following table shows how the investment was recovered:

Names of Stations	Changshou	Gongju	Yingxiuwan	Yuzixi	TOTAL
Total investment (in 100 million yuan)	1.75	5.156	1.71	1.73	10.346
Period of statistics (year)	59-79	72-29	71-79	72-79	
Installed capacity (10,000 kW)	13.95	70.00	13.5	16.00	113.45
Total power generation (100 million kWh)	111.45	160.13	45.64	24.00	341.22
Accumulated fund (100 million yuan)	7.05	10.41	2.95	1.56	21.97
Accumulated Fund/Total Investment (100 million yuan)	4.03	2.02	1.73	0.90	2.12

Most of the above are backbone large and medium-size hydropower stations in the present power system. Besides supplying electricity to the province, they are also responsible for peak adjustment, frequency modulation and backing up equipment failures. Thus they all play important roles in improving the operation of the system, raising its economic benefits, saving coal, changing the energy structure and promoting industrial and agricultural production.

Despite our great hydropower achievements in Sichuan, we sill have many problems requiring urgent study and solution. For example, we may mention the frequent changes in the energy policy and electric power policy, the lack of comprehensive planning, the poor arrangements for survey and design work, the slow progress of hydropower development, the failure to use Sichuan's superior water resources to better advantage, and so forth.

In this article we are attempting to express our views on the existing problems in planning for Sichuan's hydropower with the hope that it will attract the attention of the leading comrades in the departments concerned so that through discussion we can achieve a unified understanding and adopt effective measures to improve our hydropower planning, especially the planning for the principal rivers and the long-range planning. This will help create favorable conditions to accelerate Sichuan's hydropower construction.

1. Problems With River Planning

River planning is the basis for site selection and the compilation of long-range planning data for hydropower construction. According to the capital construction procedure, river planning should take place ahead of hydropower survey and design. When the planning has been completed and approved by the higher authorities, we should carry out the preliminary design for the cascades which are recommended in the planning as being ready for exploitation in the near future.

Certain stipulations concerning the substance and details required for river planning, particularly the need for a geological survey as a necessary step in the selection of damsites in various cascade projects, were made back in the early 1950's in a technical and economic report. These requirements have been reiterated by the ministry and the institute on many subsequent occasions. In June 1980, the Ministry of Electric Power Industry also clearly made stipulations to the same effect, according to "Opinions Concerning Division of Design Procedures for the Construction of Large Hydropower Stations into Different Stages and the Tasks and Content of Each Stage (First Draft)." Our institute basically began following these stipulations in our work soon after its inception in the 1950's. After 1958, however, everything became chaotic, and the following problems have remained for a long time:

First, the quality of surveying is not up to the required standard. For many years, we have heard the suggestion that in river planning, it is unnecessary for geological work to be carried out on all cascades as long as on-the-spot inspection and several discussions by people in the departments concerned take place. As a result, some sites in certain river courses were hastily selected, usually without regular river planning or study, and approved by the higher authorities. Then large-scale prospecting for the stage of preliminary design is carried out. Sometimes, people first try to work according to the requirements of the planning stage, but later insist that since it is not easy to find a site and that moving the families of the geological prospecting teams is difficult, it would be better to continue their work at the site already selected instead of moving to a new location. Practice has proved that this method can only double the workload and reduce the fruits of labor. This is a case of "more haste, less speed" which does not help speed up hydropower development. For example, when our institute planned for the Daduhe in the past several years, after repeated surveys, we held that conditions were favorable at the cascades in Dagangshan. So some comrades began to favor the idea of doing some work there, even to the point of making the preliminary design. At a later stage, however, it was discovered that the geological structure of the cascades, the dam area and the hydrological conditions were more complicated than we had thought. As a result, it would be very difficult to accomplish our original plan to build a dam 200-300 meters high. For the Manai Cascade on the upper reaches, we had also thought of building a dam some 300 meters high to form a "dragon head" reservoir with a capacity of some 10 billion cubic meters upstream so that the guaranteed power generation of the 10 cascades downstream could be increased to more than 4 million kilowatts. After preliminary drilling exploration, however, it was discovered that the overlying strata of the riverbed was too thick. (A hole 125 meters deep was drilled and still bedrock could not be reached.) Thus we had to look for another damsite nearby for comparison, and we considered building the Bobugou Dam on the middle reaches of the Daduhe as a supplementary project (reservoir capacity of 4.72 billion cubic meters and installed capacity of 2.5 million kilowatts). In another instance, on the lower section of the Yalongjiang near Jinping, we tentatively worked out a plan for five-stage exploitation based on a small amount of data from surveys and prospecting. Our main hope was to build a reservoir regulated by a high dam on the lower reaches at Wali. However, because of transportation difficulties and our inadequate prospecting force, investigation of the three upper cascades cannot be arranged even now and the plan for five-stage exploitation has to be postponed indefinitely. In planning for the Jinshajiang, investigation of most of the cascades has not yet begun, and even planning for the lower section below the Dukou have not been completed. Yet some leaders have directed that certain sites be included in the preliminary design. Since these sites require a huge amount of engineering work and the geological conditions are poor, there will be many technical difficulties and it is hard to determine when this project can ever be started. Yet concentrated efforts are being made to work out the preliminary design. This will certainly affect the work of investigation and design for other sites which can be exploited in the near future. Whether such action is justifiable deserves serious study.

Long experience has shown that river planning and the first phase of engineering cannot be done well if, instead of carrying out the necessary geological surveys on the main cascades of a river, especially a large river, we rely on only a few inspections of work on only a few cascades. In fact, work on several principal rivers of Sichuan has been on and off and has been a subject of discussion for more than 20 years. Yet to date, no formal, relatively complete report on river planning has been compiled. As a result, there have been many changes in the selection of sites and repeated setbacks, causing not only the loss of good opportunities, but also great waste. We should conscientiously draw our lessons from this experience.

Second, there is a lack of objective and realistic research work on the method of river exploitation or cascade planning. For a long time the plans for river exploitation have been disrupted by certain ideological trends. For example, in the early 1950's, we overemphasized the need to follow the general planning for the Changjiang and to carry out flood prevention on the lower reaches. We also overemphasized the importance of full utilization of water resources, and thus arrangements were made for the building of large reservoirs with high dams on the Jialingjiang and Minjiang in Sichuan. In the late 1960's, the major three-line construction program stressed the need for preparedness against war, and in hydropower construction and we had to implement the policy of "mountains, decentralization and caves." Furthermore, Sichuan was influenced by the water conservation policy of giving priority to the use of motorized irrigation, and instead of building large reservoirs with high dams, we overstressed the merits of water pumping and underground plants. None of these plans suited the objective reality; instead, they brought damage to planning and designing for hydropower construction in Sichuan. Thus we were forced to do supplementary or remedial work later. From this experience, we have realized that the forms of river exploitation and the plans for cascades must be based on the natural and economic conditions of the rivers themselves, and that the measures carried out should suit the local conditions. We must not come to any decision until we have completed serious investigations, comparison and demonstrations.

Third, there is the question of river planning and comprehensive utilization. River water is an asset of the state and the people, and different departments and people from different quarters have different ideas about exploiting and utilizing them. In river planning, we should implement the principle of comprehensive utilization, and then, after economic comparisons, put forward a plan that calls for less investment, yields greater benefits and conforms to objective reality. We should all heed this question and thus work together in harmony. However, this was generally overlooked in the 1960's, and particularly in the 1970's. This mistake had a direct effect on the progress of river planning. The repeated appeals from our comrades regarding this matter have so far failed to attract the attention of the departments concerned or the high-level leadership. Let us take planning for the Jinshajiang for example. In a symposium held in Beijing in 1978 on the Jinshajiang, the participating comrades unanimously agreed that the comprehensive utilization of and planning for such a large river is an important and complicated matter. Thus the minutes of the symposium stressed that "in planning the exploitation of the Jinshajiang Valley, we should implement the principle of comprehensive utilization with power generation and flood prevention as the primary objectives, while developing navigation, log floating and irrigation at the same time." To facilitate the harmonious cooperation of the departments concerned, the "minutes" added that "to further ascertain the conditions for the exploitation of the Jinshajiang, to understand the requirements of various sectors of the national economy in the exploitation of this river, and to carry out further planning, survey and design work, it is suggested that the Ministry of Water Conservancy and Electric Power ask the State Planning Commission and the State Economic Commission to organize and take charge of a number of work teams, in which the ministries, commissions and provinces concerned will participate. These work teams should proceed to the Jinshajiang in May or June of the current year (namely, 1978) for a repeat on-the-spot survey." Since these measures have not been carried out, the planning for the Jinshajiang still cannot proceed under unified leadership. Nor have the departments concerned been able to jointly undertake this task. Since our institute's independent action in planning for the section from Dukou to Ipin did not produce the desired result, we once again approached the higher authorities in 1979 with the request that a unified leading body be formed of people from the departments and provinces concerned to carry out planning for the whole river and for its comprehensive utilization. We also requested that a staff office be established under this leading body to speed up the river planning. Later, the higher authorities said that since there were difficulties in carrying out such measures, we should first directly contact the units concerned in order to arrive at a common understanding, and that we should leave some leeway in the setup for cascades. At the same time, our institute was required to submit a planning report for that section of the river as soon as possible. In practice it will be difficult for the river planning to be successful if we work according to this directive, because we will not be able to meet the requirements of Document Gui [6016] No 56 issued in 1978 by the former Ministry of Water Conservancy and Electric Power concerning planning for the Jinshajiang, which points to the need to "implement the principle of comprehensive utilization of the river, to select a rational program of action and a procedure of exploitation, and then work out a preliminary design for future." Planning for the Daduhe, the Yalongjiang and other large rivers have also faced similar problems.

Fourth, the exploitation and utilization of water resources have been handicapped because we had no regulations to go by in dealing with such matters as compensation for inundated land and relocation of people. Most of the water power facilities already set up in Sichuan are in the form of power stations of the runoff type. If we take a long-range view of the situation, the repair and construction of some hydropower stations with regulated reservoirs is certainly necessary as a means of fully and rationally utilizing water resources, meeting the requirements of the power system, and bringing into play the flexibility of water power operation. However, in the absence of a unified ruling on compensation for inundated land and relocation of people, it will be difficult to proceed with the work of planning. This problem has already slowed down hydropower construction. The Baojusi Power Station of Sichuan, for example, has a suitable capacity (640 kilowatts) and is close to the load center. Its preliminary design has been approved and the state has included the project in the construction plan. The leadership and departments concerned discussed and studied the question of inundation many times, but in the end failed to find a solution to the problem of compensation for the inundated land and the relocation of people. Consequently, the project could not be started.

Sichuan has a large population and little land (approximately 1 mu per person), and we must handle the question of inundation with extra caution. Yet if we have to make full and rational use of water resources, the inundation of some land is inevitable. We must lose something before we can gain. We hope the departments concenred at the higher levels will find a solution soon to the problem of compensation for inundated land and relocation of people, by working out relevant regulations.

Fifth, electric power and system planning cannot keep pace with the requirements of river planning, and there is a general lack of harmony. There are large power stations along the large rivers in Sichuan and the southwest. The direction of power supply from the projects soon to be started and the scale of the supply involve a wide range of factors. The Ministry of Electric Power Industry and the state have many times envisioned the supply of electricity from the west to the east, or to eastern China or the central-south. In consideration of the national balance of energy resources and in the long-range view, such a vision is undoubtedly correct. However, since there is still not a concrete long-range plan, many problems in our specific jobs cannot be studied. For example, there are such questions as: When will electricity be transmitted from the west to the east? Where will it be transmitted? How much will be transmitted? Should there be a guaranteed amount or some seasonal variations? What are the relationships between the three southwestern provinces? And so on. We need to do some real work in these respects. If people simply raise a strategic and visionary slogan and are in a hurry to see some action, it is very difficult for the vision to materialize. Furthermore, since it is only a vision, it is impossible to take into serious consideration such problems as river planning, the direction of power supply from the first stage of work, and how to connect the power grids. Then there is the problem of coordination between river planning and long-range planning for the electric power system, and this problem deserves serious consideration.

2. The Question of Long-Range Planning for Hydropower

Respect for science, seeking truth from facts, and linking theory with reality--this is a correct ideological line nurtured and fostered by our party for a long time. Yet in practice, for a long time it has been disrupted and sabotaged. Following the antirightist struggle in the 1980's, leftist ideas began to develop, and during the 10 years of catastrophe, idealism and metaphysics ran wild and reached an unprecedented height. The leftist ideological line not only affected the party's general and specific policies but also permeated various aspects of economic construction. In the field of electric power industry and hydropower construction, the formulation of general and specific policies and long-range plans were seriously disturbed.

As shown in the energy policy: Formulation of policies for energy resources and electric power should be based first of all on the conditions of material resources. These policies should be far-sighted and the measures taken should be adapted to local conditions. However, the repeated setbacks to our energy and electric power principles and policies have resulted in the present energy crisis and power shortage, as most vividly shown in Sichuan. Around 1960, Sichuan enforced the policy of "stressing thermopower," which was a serious blow to hydropower development. Even then, the development of thermopower failed to make any headway. In the 1970's, we placed our "stake" on natural gas. However, instead of living up to our expectation, the development of natural gas even became a drag on coal development. The failure of hydropower, natural gas and coal to make headway has become a difficult problem of power shortage now and for the future.

As shown in long-range planning for hydropower development: A review of hydropower planning in Sichuan shows that our work was fairly practical and effective during the first 5-year plan. In striving for high targets during the Great Leap Forward, dozens of hydropower projects were simultaneously started, causing serious waste. In the mid-1960's, when national economic planning was readjusted, we carried out a great deal of study and investigation in coordination with the three-line construction requirements. In selecting sites for hydropower plants, we had to see that these sites were suitable for the requirements of the national economy and our technical level. The sites selected at Gongju, Yingxiuwan and Yuzixi were appropriate in scope, and the power plants were completed in the 1970's with remarkable success. The national economy was seriously disrupted during the "10 years of catastrophe" with disastrous results; yet, in spite of all difficulties, our institute leadership and the broad masses of workers and staff members managed to carry out planning for some small and medium-size rivers and site-selection at Xizang and Dukou. In the first 2 years after the downfall of the "gang of four," the 10-year plan embodied a leftist rash advance, calling for large bases and high targets, including the construction of 20 large hydropower stations begore 1985, and a total national installed capacity of 500 million kilowatts before the year 2000. The task of designing for the generation of 4,000-5,000 kilowatts out of the 150 million kilowatts of hydropower devolved on our institute, with the result that in the past several years we have had to work entirely on large rivers and large power stations. There are many problems with the practice of undertaking only large projects: 1) Heavy investments: according to the original planning, Sichuan will have to invest an estimated amount of more than 50 billion yuan in the next 20 years, averaging 2.5 billion yuan a year. 2) Long construction period: the construction of each power plant from scratch to the time of power generation requires approximately 10 years. 3) Technical complexity and difficulty: This applies to large stations of 1-10 million kilowatts. As we can see now, such planning is obviously divorced from reality.

In view of these problems, we have repeatedly voiced our views with the hope that instead of placing all our hopes on large stations, we will take our lessons from the good experiences of foreign countries and the many provinces and regions in our country so as to bring about a combination of large, small and medium-size projects; and that aside from the large power station at Ertan, we should actively speed up our planning for medium-size rivers and site selection in the near future. However, there is still no unified understanding on these views, because people are talking about the difficulty of moving homes, inadequate resources, or the problem of work division as excuses instead of taking positive action. Now, if we continue to procrastinate instead of adopting resolute measures immediately, we will miss the good opportunity afforded by the readjustment in the next several years, and as a result, neither the large nor the medium-size projects can be successful. Sichuan's hydropower development will be in a more passive position with even more serious consequences.

3. Several Views and Proposals

First, in both theory and practice the leading organs should attach great importance to the work of planning. Particularly in the very near future, we hope the leadership will devote more energy to general planning instead of being immersed in specific technical or vocational work, and thus overlooking the matters of strategic importance. First of all, the leading units should determine to eliminate the pernicious leftist influence. On the basis of summing up their experience, they should work out some necessary rules, regulations and laws, such as regulations for river planning, methods of work coordination in comprehensive utilization and apportionment of investments, rules to compensate for inundated land and relocation of people, and so forth. The leading departments should resolutely carry out the relevant decisions and, in case of any violation of rules and regulations, trace the responsibility even to the point of legal prosecution. In the case of river planning, for example, when planning is part of the process of capital construction and design, the higher authorities should relay the planning documents to the lower levels and exercise constant supervision and inspection. A planning report officially approved should be legally binding, and no department or individuals whatever should be able to change or disrupt it. Furthermore, the work of planning includes comprehensive local planning, electric power planning and river planning and involves many fields because of the many significant factors and different methods of coordination. Therefore, some advanced theory, such as systems engineering, and advanced computer technology should be employed for analysis and demonstration. It is suggested that the departments in charge at the higher levels should, after certain experimentation, raise the professional level, both theoretical and technical, of the planning personnel so as to create better conditions for the work of planning.

Second, in dealing with the work of planning for hydropower in Sichuan in the near future, the following suggestions are offered:

1. In river planning: Among the three large rivers--Jinshajiang, Yalongjian and Daduhe--work on the Jinshajiang can be temporarily halted in 1981 until the supplementary planning report on the Dukou-Ipin section is completed. Then in the following years, we should concentrate our efforts on completing the planning for the Daduhe (below Shuangjiangkou) and the Yalongjian (below Wali), and then submit a formal planning report. At the same time, we should quickly take up the work of planning for the upper reaches of the Minjiang and some of the better medium-size rivers, and select some sites for medium-size hydropower stations that can be completed fairly quickly.

2. In selecting power resources: At present, we should carefully study the question of a combination of large and medium-size projects and attempt only the possible. The scope of a power station should be commensurate with the system's development and the state's industrial and technological levels, and particular attention should be paid to the availability of funds and the results of investments. Hereafter, for either domestic investments or foreign funds, we should allow an annual interest of 7-8 percent, so that in 10 years the amount invested will be doubled. This matter deserves great attention. There are many sites suitable for large power stations in Sichuan. Since the state wants to develop hydropower, the construction of some large backbone power stations is necessary. Prospecting, design and scientific research for the Yalongjiang and Ertan stations should be continued so that they can be qualified for inclusion in the state plan. However, in view of the actual conditions in our country at present and the arduous and complex nature of large power stations, we should not attempt too much. It would be even more undesirable to concentrate our resources on large power stations. For some years to come, we should build more medium-size hydropwer stations (of slightly over 100,000, several tens of thousands, or slightly over 1 million kilowatts) which require less investments and shorter construction periods but yield faster returns. Our specific proposals are: 1) For those projects at Tongjiazi on the Daduhe, the two-stage project at Yuzixi and the three-stage project at Nanyahe, we should increase our investments and speed up their construction in order that they can be in operation as soon as possible. 2) Since the preliminary design for the Baojusi Power Station has already been approved and because it has an annually regulated reservoir and is close to the load center, work on it should be started as soon as possible. 3) The preliminary designs for the Pengshui Hydropower Station on the Wujiang and the Tongzilin Power Station on the Yalongjiang, and research on the exploitation of the upper reaches of the Minjiang should be expedited. 4) There are still some small and medium-size hydropower stations with fairly favorable conditions, such as the Longhe Cascades, the estuary of the Hezhouhe and the estuary of the Luojiang. Our institute and the units concerned in the province should be allowed to express their views on the construction. If they can meet the requirements, we should consider a joint undertaking by the ministry, the province and the region. This will arouse the enthusiasm of people in various quarters and promote the development of hydropower construction.

SICHUAN COAL PRODUCTION CUT TO PERMIT NEW POLICIES TO BE IMPLEMENTED

Chengdu SICHUAN RIBAO in Chinese 15 Apr 81 pp 1, 2

[Article: "Speed Up the Pace of Readjustment, Increase Coal Output as Soon as Possible."

[Excerpt] Actively handling well the internal readjustment of the coal industry in order to coordinate and continuously increase coal production in the next several years, and concentrating on present production and maintaining a set production quota to assure a supply for basic coal demand for our people and the various branches of the national economy, are the urgent assignments of Sichuan's coal industry during the implementation of the readjustment policy of the national economy. Whether or not these assignments are accomplished will affect the overall situation of the national economy of our province.

Under the leadership of the Communist Party and with the efforts of the miners, Sichuan's coal industry has been successful both in production and construction. We have rebuilt many old enterprises and built a number of new key enterprises. All these enterprises and some small coal mines that are owned by the counties and the people's communes form a certain scale of productive capacity. This has made great contributions to the supply of coal for industrial and agricultural production and for the daily life of the people. For many years, however, many problems have existed in the coal industry due to the effects of "leftist" thought. Its major expressions are: emphasizing extraction while downgrading excavation; an imbalance between extraction and excavation; extracting rich deposits while ignoring poorer grades; an imbalance between extraction of higher seams and extraction of lower seams; stressing production and ignoring safety; lacking safety facilities; using incomplete sets of links in the production chain; putting production before the well-being of the masses; lacking welfare facilities, etc. Since the third plenary session of the Communist Party, Sichuan's coal industry organizations have implemented the national economic readjustment policy. We have fulfilled the national coal production plan. At the same time, we have made every effort to conduct the internal readjustment task. The serious disproportion between extraction and excavation in some coal mines has been changed. To sum up, however, the readjustment task is still a formidable one; imbalances and unsafe conditions have not been entirely corrected. We must, therefore, take a clear-headed approach and try in every possible way to handle well the internal readjustment of the coal industry. We must greatly speed up the readjustment and various consolidated tasks and strive to coordinate various internal relations within three to five years, guaranteeing that coal production will continuously increase in the days to come.

Coal is an important energy source. It provides almost 70 percent of our energy and occupies first place in Sichuan's energy structure and, therefore, affects all trades and professions and the lives of the people. We may say that whether or not the readjustment and the production of the coal industry will be handled well will directly affect the further readjustment of the national economy and the stability and unity of national politics. During the entire period of the national economic readjustment, coal production cannot slow down. We will try in every possible way to speed up the readjustment and to make every effort to increase coal output to fulfill the national plan. Now, some comrades lack a correct understanding of the readjustment policy, believing that readjustment means "slow down" or cutting production and decreasing output. They do not try their best to fulfill the plans that can be fulfilled through their efforts. It should be recognized that there are a lot of difficulties in the fulfillment of the readjustment and production assignment because the tasks are arduous. Nevertheless, the objective of bringing the issue out into the open is to let us keep a clear head and actively overcome the difficulties. We must depend on the wisdom and the strength of the masses and adopt various effective measures to overcome the difficulties. Some of Sichuan's major coal mines, such as Tianfu, Songzhao, Furong, and Jiayang, have achieved great successes both in readjustment and production and become our good models since they adopted such active steps. Naturally, for those mines that have a serious imbalance and are assigned very difficult readjustment tasks, it is necessary to arrange a lower production quota in order to let them speed up the readjustment. As a matter of fact, this year's national coal production arrangement has considered the factors of readjustment and allowed for unforeseen circumstances. Although we have not set high targets in production, we will not allow somebody to reject or to make no effort to fulfill some targets that can be realized. We should note that coal production has great potentialities. There are favorable factors for maintaining the present production quota and fulfilling this year's plan.

COAL PRODUCTION IN FURONG MINE BUREAU OF SICHUAN PROVINCE TOPS PLAN

Chengdu SICHUAN RIBAO in Chinese 15 Apr 81 p 1

[Article by Peng Dongyuan [1756 2767 0337] and Wang Jiyuan [3076 4949 0337]: "Leading Cadres Go Right to the Front Line To Handle Readjustment and Production Tasks; Furong Mines Bureau Overfulfills First Quarter Coal Production Plan"]

[Text] The leading cadres at all levels of the Furong Mines Bureau have gone right to the front line of production, led the staff and workers to study and to implement the spirit of the Central Committee Work Conference, pooled their wisdom and strength to overcome difficulties, and brought about a continuous increase in raw coal output. In the first quarter of this year, raw coal output of the whole bureau overfulfilled the national plan by about 6.75 percent; the average daily output increased from 4,356 tons in January to 5,026 tons in March. This has given strong support to industrial and agricultural production, and to the supplies of coal needed daily by the people.

Among the coal mines under this bureau, most were built and put into production during the ten years of chaos, so irrational design, compounded by subsequent proportional imbalances between extraction and tunneling, resulted in fairly substantial production difficulties. At the beginning of the year, the coal output of whole bureau slumped. In order to put an end to this passive state of affairs, the leading cadres of the bureaus and the mines paid more attention to the front line of production, led the comrades from the production, technical, and safety departments in going down to the mines, getting together with the masses of staff and workers, studying the documents of the Central Committee Work Conference, researching and solving various ideological problems and key production problems, and organizing and conducting production activities. This year, the Shanmushu coal mine, in which production conditions are extremely difficult, increased its total drifting footage. Some of the staff and workers were afraid of the difficulties involved in carrying out the readjustments and completing the production tasks. The leading cadres of the bureau and the mine often went down to the grass-roots units, organized staff and workers to discuss current favorable situations, explained the important role of the coal industry in the national economy, and taught all staff and workers to work hard for the nation. At the same time, they investigated the situation down in the mines, strengthened the dispatch control, handled well the shift relief on the coal face, supplied equipment, fittings, and materials which were urgently needed in extraction and tunneling, and improved the production management and reward system. Spurred on by the leadership, all staff and workers of the mine have heightened their confidence and enhanced their morale. In the first quarter of this year, they not only overfulfilled the drifting and tunneling footages, but also overfulfilled the raw coal production plan. The Baijiao coal mine is a big mine with the "five dangers," i.e., water, fire, gas, ground pressure, and coal dust. A few of the cadres were overly cautious in their approach to production. Faced with this situation, the leading comrades of the bureau and the mine went down to mine areas, teams, groups, and shifts to help everyone detect hidden hazards, to strengthen rectification and reform efforts, to build safe facilities, and to build a sound safety responsibility system. As a result, in the first quarter of this year, this mine had no fatal accidents and reduced industrial injuries. At the same time, they overfulfilled the raw coal production plan.

Facing a situation in which ultra-left ideological influences had led to overemphasizing extraction and underemphasizing tunneling, with the result that there was an imbalance between them, the leading cadres at all levels of this bureau, during the course of joining the front lines of production, handled the readjustment tasks well and created good conditions for coal production. Based on on-the-spot mine investigations, they have reformed this year's readjustment plan, taken speeding up the drifting and tunneling footages as the current focal point of the work, and correspondingly added some facilities. The bureau, mine, and area have each assigned one chief cadre to oversee drifting and tunneling. They also augmented the technical staff and management cadres to handle the drifting and tunneling tasks and formed a working system in which a dispatching meeting of drifting and tunneling would be held in order to periodically check up the task. The chief management cadres personally organized and supervised the main projects concerning the coordination of the proportion between extraction and excavation. They also carried out four fixed method, i.e., fixed schedule, fixed shift time, fixed construction manpower, and fixed materials and equipments; therefore, manpower, materials, and finances have been assured. The first quarter of this year, the drifting and tunneling footage of this bureau has reached 12,893 meters. It has obviously promoted the coal production. Because the leading cadres of the Communist Party Committee of Xunchang coal mine conscientiously implemented the policy about "develop both extraction and excavation, and drifting should go ahead of rests," the coal output, the drifting footage, and the tunneling footage have all overfulfilled the plan, in which the footage of March has topped 1,000 meters and is the highest record since this mine was built.

Beginning from February this year, according to the reward policy of the higher authorities and the situation within the bureau, this bureau have changed the past reward method that gave basic awards to the production units, and apply a new method that gives awards depend on how much the production unit has overfulfilled the production target. At the same time, they also combined overfulfillment target, safety, and quality control together for the consideration for reward to all levels of cadres; therefore, the enthusiasm of staff and workers has been further aroused. Every staff and workers have made efforts to overfulfill the plan and to ensure safety. The readjustment steps have been accelerated, and the continuous growth of the coal production has been promoted.

BRIEFS

JIANGSU HYDROELECTRIC POWER STATION--As of now, 172 small hydroelectric power stations have been built in Jiangsu's rural areas, capable of generating 62 million kw/hr of electricity per annum. Most of these hydroelectric power stations are scattered in Xuzhou, Huaiyin and Zhenjiang prefectures of the province. [OW041721 Nanjing Jiangsu Provincial Service in Mandarin 1100 GMT 1 Aug 81]

QINGHAI RESERVOIR--Construction of (Qingjiazha) reservoir in Ledu County, south of the Huangshui River, started in January 1978 and finished at the end of July 1981. The capacity of the reservoir is 4.55 million cubic meters. The quality of the construction work is above state standards. [SK070140 Xining Qinghai Provincial Service in Mandarin 2330 GMT 4 Aug 81]

QINGHAI COMMENDS LOGISTICS COMPANY--Listeners: Twenty-four cadres and fighters of the fourth company under a certain vehicle regiment under the General Logistics Department stationed in our province bravely rescued miners at the (Gaoqian) colliery on 20 April 1981. This station introduced their deeds on 10 June. A certain section under the General Logistics Department recently convened a victory rally to commend (Qiu Jiahui) and 23 others for their heroic deeds. They were conferred certificates of merit and awards. A silk banner was awarded to the fourth company. (Chen Yi), deputy political commissar of the General Logistics Department, made a special trip to our province to attend the rally. A resolution adopted by the section under the General Logistics Department on launching a campaign to emulate Comrade (Qiu Jiahui) and the 23 others was read at the rally. BRIEFS

GENERAL PACKAGING CORPORATION--Beijing, 3 Aug (XINHUA)--The China General Packaging Corporation has been established to help manage and guide packing and packaging operations throughout the nation, according to the State Economic Commission. The new Beijing-based corporation will be responsible for formulating and implementing principles and regulations for the industry, establishing long-term and annual development programs and improving industry techniques. It will provide consulting services and help train cadres and technical personnel. The corporation encourages packing and packaging enterprises and their auxiliaries, container manufacturers, paper, timber and other raw material supplies, to merge and streamline their operations and raise production efficiency. The corporation will be engaged in compensatory trade and joint ventures for the production of packaging facilities. [Text] [Beijing XINHUA in English 1233 GMT 3 Aug 81]

SICHUAN INDUSTRIAL PRODUCTION--Sichuan Province's total industrial output value in June was 8 percent more than in May. The province's textile industrial output in June was 4.5 percent greater than in May. The No 2 light industrial output in June was 6.4 percent up and industrial output of communes and brigades was 33.5 percent up. Output of bicycles and watches was 38.9 and 10.9 percent up respectively. The province's heavy industrial output in June was 9.6 percent more than in May. FOREIGN TRADE

GUANGDONG FOREIGN TRADE INCREASES DURING FIRST HALF OF 1981

Guangzhou NANFANG RIBAO in Chinese 8 Jul 81 p 1

[Article by correspondents Jiang Defen [1203 1795 4248] and Luo Liangyong [5012 5328 3057]: "Gratifying Achievements of Guangdong in Foreign Trade--Foreign Exchange Earnings from Exports in First Half of 1981 Hit All Time High"]

[Text] Guangdong achieved gratifying results in foreign trade in the first half of 1981. Compared with the same period in 1980, the total value of procurement for foreign trade increased 10.1 percent, and the total amount of foreign exchange earnings from foreign trade increased by 28.8 percent. These are unprecedented records for the first half of any year. Guangzhou Municipality; Shantou, Huiyang, Foshan, Chaoxing and Zhanjiang Prefectures; Hainan Administrative Region; and Shenzhen and Juhai Municipalities have all fulfilled more than one half of their assigned quotas.

Since the Third Plenum, the adoption of flexible economic policies in the countryside has brought about a sustained development of agriculture and diversified economy, and thereby laid a material foundation for export. Thanks to the national economic readjustment, there are now steady supplies of light industrial, textile and handicraft goods.

The proportionate sharing of increased foreign exchange earnings as arranged by the central government for this province has greatly enhanced the enthusiasm of various departments at all levels in promoting foreign trade. Many areas in the province have shown increased production and obtained larger shares of foreign exchange earnings, which, in turn, could be used to further promote production and then foreign trade. In order to produce more readily marketable commodities which would bring in more foreign currency from export, the provincial government has appropriated more than $100 million out of its retained share to support the production and development of export commodities according to the policy of "supporting exports with imports." The foreign trade departments at various levels have actively supported the production of more than 100 commodities through processing imported raw materials and assembling imported parts, exchange of materials, negotiated prices, subsidies for selling at special prices, proportionate sharing of foreign exchange earnings and other flexible measures. There has been a sustained growth in such highly competitive commodities as drawn work, fishing nets, firecrackers and fireworks, corrugated paper, various types of furniture, and cotton cloth according to the tradition of "supporting exports with imports." The export value of the newly developed ceiling fans and peanut oil has respectively trebled and doubled that of the previous year.

Furthermore, all foreign trade enterprises have paid greater attention to the study and investigations of the world market in order that the exported commodities could be sold at good prices and thus bring about more foreign exchange earnings. According to a comparison of statistics on 10 principal commodities in the first half of 1981, the average selling price was increased by 15 percent over that of the same period in 1980. This increase means an increase of $40 million for the state in foreign exchange earnings.

CHINA SELLS CRANE SHIPS TO ROMANIA

Langfang CHUANBO SHIJIE [SHIP WORLD] in Chinese 1 Jul 81 p 2

[Article by correspondent Liu Dajun [0491 1129 6874]: "Four Crane Ships Exported to Romania by China Already Delivered"]

[Text] On the afternoon of 15 May, the well-lighted Heping Hall of Heping Hotel in Shanghai was the scene of a signing ceremony whereby the 50-ton crane ships exported by China to Romania were formally delivered. Responsible leaders of China National Machinery Import and Export Corporation, Shanghai Shipyard, Jiangnan Shipyard and the Ship-Inspection Bureau of China; and the engineering and technical personnel of the delivery-check group of Romania were present at the ceremony.

This was the first time that China exported crane ships to Romania. The exported fleet consists of four ships ordered by Romania and built by Jiangnan Shipyard. The main technical data are as follows:

Total length: 40.5 meters;
Length between two posts: 40 meters;
Model Width: 20 meters;
Maximum Width: 20.5 meters;
Model Depth: 3.4 meters;
Draught: 1.6 meters;
Displacement: 1 ton;
Type of crane: 356-degree turning;
Time for a full turn: 4 minutes;
Lifting strength: Main boom: 50 x 28 x 4.7 (ton x meter x meter/minute);
Auxiliary boom: 10 x 30.5 x 25 (ton x meter x meter/minute);
Hoisting height: Above water surface, 28 meters;
Below water surface, 12 meters;
Crew: 19 persons.

Each ship is equipped with many diesel generating units for both illumination and power. There are also cabins for single persons, two persons and four persons, in addition to kitchen, mess hall, broadcasting saloon, restrooms and other facilities of daily life.

These 50-ton crane ships are not automatically piloted. They were constructed according to the scope of our ZC steel ships, under the supervision of China Ship Inspection Bureau as entrusted by Romania. In the course of construction, Jiangnan Shipyard has demonstrated its high skill and great energy, and the fine quality of construction won favorable comments from the Romanian delivery-check group.

In the past several years, there have been rapid developments in Romania's foreign trade and shipping. Its large-scale oil prospecting equipment and petrochemical refinery equipment are particularly well-known. In view of the continued increase of export, this fleet of crane ships will play a positive role in speeding up loading and unloading at the harbors.

BRIEFS

SHAANXI-GANSU-NINGXIA HIGHWAY--Lanzhou, 21 Jul (XINHUA)--After inspection by the state capital construction commission, the Yichuan-Lanzhou highway, the longest in China's loess plateau, was formally opened to traffic on 21 July. The 949.8-km highway starts in Shaanxi's Yichuan County, passes through Gansu's Qingyang and Heshui counties and Ningxia's Guyuan and Xiji counties and ends in Yongjing County in the vicinity of Lanzhou, Gansu. The highway has over 100 bridges and passes through 4 medium-sized tunnels. Started in 1972, the construction of the highway was stepped up after the downfall of the "gang of four." GENERAL

TOWNSHIP OF BAIYUNHUSHI IN NEI MONGOL DESCRIBED

Beijing DILI ZHISHI [GEOGRAPHICAL KNOWLEDGE] in Chinese No 5, May 81 p 14

[Text] A new town, the township of Baiyunhushi, in New Mongol has risen in the hinterland of the Koerqin grasslands since the Tong-Huo railway (from Tongliao municipality to the Huolinho coal mine) was opened to traffic. With a population of more than 20,000 the township has an area of 7.5 square kilometers, with the Han Mountain in the north, the remaining range of Daxinganling, and the Hulin River in the south. It has a good environment and a beautiful landscape.

Baiyunhushi was formerly known as Heidamiao, which was built 240 years ago. In the age of feudal rule, when government and church were one, there were five temples with 500 lamas there. The temples were the most important within a radius of several hundred li.

In 1962, its name was changed to Baiyunhushi as the seat of the committee for Xieyouzhong banner. The people of various nationalities worked hard for more than 10 years to build the township. A 5-li asphalt road broad enough to accommodate four trucks runs east-west through the township and rows of cinemas, stores, banks and hotels line the streets. Government organs, schools and residential quarters are well laid out, and factories and workshops are spread throughout the township area. Attaching great importance to culture and education for minority nationals, the party and government have set up five primary schools, three middle schools and a teacher's college.

The Baiyunhushi railway station on the Tong-Huo line has taken shape and is now a hub of communications for goods and passengers. A 370-km high-tension power transmission line provides electricity to the agricultural and pastoral areas. Industries for making and repairing agricultural and stockbreeding machinery, producing dairy products and making shoes have sprung up. The former leather and skin cooperative, which could produce only harnesses in the past, is now a leather factory with more than 200 workers. Its high-grade products, such as gloves and leather suitcases, are well-known throughout the country and are sold overseas. The total value of the township's industrial output has risen from several hundred thousand yuan at the early stage to nearly 10 million yuan.

TOWNSHIP OF DAHUSHAN IN LIAONING PROVINCE DESCRIBED

Beijing DILI ZHISHI [GEOGRAPHICAL KNOWLEDGE] in Chinese No 5, May 81 p 14

[Text] The township of Dahushan is situated in a locality 18 li south of Heishan County, Liaoning Province. North of the township is the Houdahushan, 142 meters above sealevel. It is only some 10 li from Height 101 east of the county seat at Heishan and is the gateway guarding Jinzhou, a place of strategic importance. In the center of the township is a hill, Hushenshan [Tiger Body Hill], which is surrounded by urban areas. The northern part of Hushenshan is known as Hutoushan [Tiger Head Hill]. Looking down from the top, the two hills look like a crouching tiger. At the foot of the Hushenshan is beautiful West Lake.

At about the time the Daheishan Fort was built in the Yuan Dynasty, Dahushan was inhabited, but there was no record of the place until the Ming Dynasty. The Heishan County annals record: "The locality 18 li south of the city was known as the Daheishan Fort in the early years of the Qing Dynasty. It is at the center of the Fengtian-Shanhaiguan railway and is the starting point of the Da-zheng railway and contains transportation facilities. There are a great many government offices there, business is thriving, and business firms are increasing in number. The prospect for its development is promising. It is the southeast gate of the county." At the dawn of liberation, it had a population of about 10,000 and only small handicraft workshops such as oil mills and vermicelli factories. It was not until the early sixties that some small enterprises were added. Industry has grown rapidly in recent years: paper mills, steel-rolling mills, refractory materials plants, and grain, oil and foodstuff processing plants have been built. The population has grown to 25,000.

Dahushan is the converging point of the Shenyang-Shanhaiguan and Dahushan-Zhengjiatun railways and a busy railway transport center. It is a hub for the exchange of goods with areas inside the Great Wall. Among the transportation facilities, bus service is maintained with outlying municipalities and counties.

SECOND DAM TO BE BUILT AT CHANGJIANG GORGE

HK071258 Hong Kong WEN WEI PO in Chinese 6 Aug 81 p 1

[Long-distance call from WEN WEI PO correspondent Ou Ping-Chiang: "Second Dam to be Built at Xiling Gorge; Gezhouba Dam to Start Generating Electricity on 10 August"]

[Text] Yichang, 5 Aug--According to what was learned by this correspondent: with the completion of the Gezhouba Dam, preparations are under way for the construction of a second dam at a site at Xiling Gorge on the Changjiang River.

Gezhouba, China's largest water conservancy construction project, will start generating electricity on 10 August. Responsible persons of the State Planning Commission, vice ministers of the ministries of water conservancy and the electric power industry and the vice provincial governors of Hubei have already arrived in Yichang Municipality and they are ready to attend the ribbon-cutting ceremony for the official commencement of electricity generation. The Gezhouba Dam, which is situated at the mouth of the Changjiang River, has a total length of 2,561 meters across the river and is 71 meters high. It is China's largest water conservancy project and is of great benefit to shipping and electricity generation.

The first-stage construction project of the Gezhouba Dam was completed last May. The gates were opened to test the dam's capacity to flow water; and its shipping capacity was also tested last June. However, the dam was quite unexpectedly tested by a great flood of the Changjiang River early on the morning of 19 July. The flood was unprecedented over the past 100 years. At a speed of 72,000 cubic meters per second, the flood water rushed out from the three gorges and pounded at Gezhouba. The Gezhouba Dam victoriously withstood the test of the flood water.

The ceremony for the official generation of electric power by the Gezhouba Dam was originally scheduled for the beginning of last July. However, to resist the extraordinarily serious flood, it was postponed until 10 August. It is indeed a double happiness that the Gezhouba Dam officially commences electricity generation after winning a victory in fighting flood.

The total installed capacity of the two electric power stations of Gezhouba is 2.715 million kilowatts. They generate an average of 13.9 billion kilowatt-hours of electricity annually, which is equivalent to three times the electricity generated throughout the country during the initial period after liberation and is more than double the volume of electric power generated by the Liujiaxia hydroelectric power station, which was the largest in China. Through high-tension power transmission cables, the tremendous electric power is transmitted to the urban and rural areas of Hubei, Sichuan, Hunan and Henan. Over repeated trial operations and power transmission, the water turbogenerator sets have functioned normally and should be able to start productive operations on schedule.

This WEN WEI PO correspondent boarded a Changjiang passenger liner and arrived at Gezhouba through the three gorges at 7 pm on 5 August and noticed that the water level of the Changjiang River has already returned to its normal level. The water level of the Gezhouba Dam is 60 meters above sea level, some 10 meters below the top of the dam.

The Gezhouba water conservancy project is the largest water conservancy project for harnessing the Changjiang River. At present, the second-stage construction project has already started. It is expected to be completed by 1986.

The key water control project of the three gorges is the fundamental project for completely harnessing the calamities of the Changjiang and exploiting its water resources. The Gezhouba Dam is the first dam to cut across the river. The second dam to cut across the river will be built at a site at Sandouping at Xinling Gorge.

GUANGDONG, FUJIAN ENJOY GREATER AUTONOMY IN FOREIGN TRADE

Hong Kong WEN WEI PO in Chinese 29 Jun 81 p 1

[Article by correspondent Lan Jingzhong [5663 7231 0022] in Beijing: "Autonomy for Guangdong and Fujian To Be Further Expanded as a Means To Break Away From Old System and To Discover a New Road According to Decisions Made in the Special Zones Work Conference Held in Beijing--New Regulations on Demarcation of Special Zones and Construction of Airport Worked Out"]

[Text] While economic restructuring is in progress, Guangdong and Fujian, the first two provinces to implement special policies and adopt flexible measures, will enjoy greater local autonomy. These provinces will be more easily accessible to foreigners, and their policies will be even more flexible. A number of provisional specific regulations have been drafted to provide security and preferential treatment for investments by overseas Chinese and foreigners in the special economic zones of these provinces, according to information revealed by the Guangdong and Fujian Special Economic Zones Work Conference recently held by the State Council in Beijing.

This conference was presided over by Vice Premier Gu Mu [6253 3668] and attended by leading persons of both provinces including Ren Zhongyi [0117 0112 1138], Liu Tianfu [0491 3944 1133], Wu Nansheng [0702 0589 3932], Liang Xiang [2733 3276] and Ceng Dingshi [2582 1353 4358] of Guangdong; Xiang Nan [7309 0589], Ma Xingyuan [7456 5281 0337], Guo Chao [6753 6389], Zhang Yi [1728 6695] and Hou Linzhou [0186 2651 5297] of Fujian; responsible persons of various ministries, commissions and bureaus under the State Council and of various relevant departments in the provinces; and well-known Chinese economists including Xue Muqiao [5641 2550 0294], Xu Dixin [6079 3321 2450], Fan Ruoyu [5400 5387 1946], and Qian Junrui [6929 0193 3843], totaling more than 1,000 persons. The significance of this conference, held against a background of the strategic shifting of the focus in our economic work with a view to stressing the all-around importance of the central government's decision to implement special policies and adopt flexible measures in the two provinces, lies not only in giving full play to the superiority of these provinces and enabling them to become rich ahead of others, but also in the experiments of restructuring our national economy and exploring a new way of development.

The implementation of the central government's policy decision for the two provinces began in 1980. Its main contents are: an open-door policy for the provinces (meaning also the liberal use of overseas Chinese funds and foreign funds to import suitable advanced technology and methods of scientific management and the expansion of foreign trade in the provinces); the implementation of more flexible policies; and the grant of expanded local autonomy (including the decision-making power in economic, personnel and legislative affairs and the power of the enterprises to manage their own business). Outstanding success has been achieved since the implementation of this policy. In 1980, the two provinces underwent great developments in industry, agriculture and commodity economy. Their total volume of exports surpassed the best historical records (compared with 1980, these provinces' total exports increased by 32 and 47.2 percent respectively) and their retained shares of foreign exchange earnings increased by more than five times. However, it was held that in the course of implementing this decision policy, the influence from the "left" was not completely eliminated, and the mind was not sufficiently emancipated. Some authority which the central government should have delegated to the lower levels was not actually delegated, and the two provinces sometimes failed to do what they should do. Strictly speaking, it was neither "special" nor "flexible." Therefore, the conference particularly reiterated that while the whole country has been undergoing an economic restructuring, the orientation of the special policies and flexible measures for these two provinces remained unchanged. The conference called on the provinces to further emancipate their minds, boldly carry out their experiments and reforms, and continue their advance. In line with the spirit of keeping the doors of the provinces open more widely, implementing more flexible policies and granting greater decision-making power for the provinces, the conference formulated measures to promote reforms in the provinces so that their special policies could be truly special and their flexible measures could be truly flexible. These provinces will then be one step ahead of others in economic development. From what we have learned and according to the new regulations, the two provinces will have full power in handling such matters as planning, finance, banking and foreign trade for their own economic development provided the necessary centralization of power for the central government is guaranteed and the principles of an all-round balance are observed. In the system of planning, the province will occupy the dominant position; in financial matters, the system of responsibility will be enforced; and in economic relations with foreign countries, there will be greater power of decision-making for the provinces. The system of banking would be duly revised, and the power of local control over prices would also be appropriately expanded. Special consideration and more flexibility would be allowed for the market and the supply of commodities.

More Flexible Foreign Trade

The stipulations concerning economic relations with foreign countries and foreign trade can be summarized as follows: Aside from finished petroleum products, tungsten ores, and other items that are subject to limited distribution among foreign countries and to planned control at home, transactions and export of all other commodities produced in the provinces can be handled by the provinces themselves. These provinces and their organs in Hong Kong and Macao will handle all the exports to Hong Kong and Macao. The two provinces can also act as export agents for all localities, except for those goods handled exclusively by the Foreign Trade Corporation. As for imports, the provinces can approve all transactions except those for food, chemical fertilizers, foreign cigarettes and liquor which are subject to other consignment regulations. Methods for the control of payment abroad and delivery at home can be worked out by the provinces themselves. Measures for the importation of technology, joint ventures, processing and assembling materials and parts supplied by customers, compensatory trade, cooperative production, and foreign loans can all be determined by the provinces guided by relevant regulations of the central government and on the understanding that such measures will not disturb the state's overall balance.

Greater Local Power Over Personnel Matters

In accordance with the policy of delegating authority to the lower levels, the provinces will be given the necessary rights over personnel management and local legislation. Enlarged power over personnel matters means that aside from the leading body of the provincial government, the province can decide on the establishment of any structure below the provincial level and the staffing of these structures. The provinces are also permitted to recruit their required personnel from abroad or among the unemployed people at home. This power is of great significance in reforming the administrative and personnel systems and in raising work efficiency.

Another salient feature of this conference is the systematic and in-depth study and discussions on the significance, theory, system and methods of establishing special economic zones in our country. On the basis of a unified understanding, regulations were worked out to deal with various issues in setting up special zones, such as the special features and the type of special economic zones we should have, the reduction or exemption of taxes, the simplification of entry and exit procedures, labor wages, the market, domestic and foreign trades, currency and monetary control, the demarcation between special and nonspecial zones, planning for the special zones, construction of telecommunication facilities, airports and harbors, fund-raising for basic construction, legislation for the special zones, the system of guidance and control, the training of professional cadres, security measures for the special zones, and so forth.

Deliberations Over a Number of Specific Rules and Regulations for Special Zones

Accordingly, deliberations were carried out over the draft of specific regulations for the special zones. All these specific regulations embody a desire to safeguard investments and to give more preferential treatment to the investors in the form of flexible measures and simplified procedures for the effective administration of the special zones. While fully exercising our sovereign rights, we can also create better conditions and environments for investments. These regulations will be promulgated after due legislative process.

Implementing special policies, adopting flexible measures and setting up the special economic zones in the two provinces are innovations of China's new historical period, and new circumstances and new problems will be encountered in the process. Therefore, the responsible persons, particularly the policymakers, must have both courage and insight. While showing the mettle of innovators in breaking away from the old economic shackles and illogical "traditional" conventions, and in eliminating the "leftist" influences while exploring new methods, they should also seek truth from facts, be good at studying and investigating, and give full play to the role of experts and the brain trust, so that everyone will work together in harmony and advance steadily. The gratifying aspect of this conference is its great vitality serving as an inspiration for people to blaze new trails in the search for a brighter future for our country's economic construction.

Beijing, 24 June.

GENERAL SITUATION OF NATIONAL ECONOMY OUTLINED

Beijing and Shanghai ZHONGGUO BAIKE NIANJIAN 1980 [YEARBOOK OF THE GREAT ENCYCLOPEDIA OF CHINA, 1980] in Chinese Aug 80 pp 53-56

[Article by Zhang Minliang [1728 2404 2733]]

[Text] Economy

The old China was a semi-feudal, semi-colonial nation whose national economy was extremely backward. After its founding, the new China embarked on large-scale economic construction, bringing about speedy advances in its industry, agriculture and the entire national economy. Ownership of the means of production in China is primarily of two types: socialist ownership by the whole people and ownership by socialist labor collectives.

The general policy of China in developing its national economy is to "take agriculture as the foundation and industry as the leading factor." On the basis of this policy, China has formulated its national economic plans for the development of its agriculture, light industry and heavy industry, in that order. In carrying out socialist construction, China has also adopted the policy of "maintaining independence, keeping the initiative in our own hands, practising self-reliance and hard struggle, and building up the country with industry and thrift," as well as paying attention to the simultaneous development of industry and agriculture, light and heavy industry, foreign and indigenous enterprises, and large and medium-to-small enterprises, according to the principle of walking on two legs.

In late 1978, at the Third Plenum of the 11th Party Congress, an important decision was made to shift the focus of work to the realization of the four modernizations and carry out the policy of readjustment, restructuring, consolidation and improvement. This brought about a change in the sluggish national economy. The central authorities also issued two documents on agriculture. The implementation of these two documents signified the application of the party policy in rural areas, and brought some initial prosperity to the rural economy. More than 9 million unemployed urban persons found jobs. Some workers had their wages readjusted. Greater atten- was paid to the development of the textile industry and light industry, and capital construction was curtailed to some extent. Some enterprises began to enjoy greater decision-making power on a trial basis. The people improved their living conditions. In 1979, the gross value of industrial and agricultural output increased to 617.5 billion yuan, overfulfilling the state plan by 1.5 percent and showing an 8.5 percent increase over 1978. The national income totaled 337 billion yuan, an increase of 7 percent over that of 1978, based on fixed prices.

The "readjustment, restructuring, consolidation and improvement" of the national economy. During the Great Cultural Revolution, the national economy was so badly sabotaged by Lin Biao and the "gang of four" that it was at the brink of collapse. After the "gang of four" was smashed, the economy began to recover rapidly. But although the situation was changing for the better, it was discovered there was a serious dislocation in national economy. For this reason, at the 1978 work conference of the Party Central Committee, the policy of readjustment, restructuring, consolidation and improvement was adopted.

Since the implementation of this policy in 1979, China has gradually readjusted its national economy, and some initial achievements have been seen.

Agricultural foundation strengthened. In 1979, the Party Central Committee issued two documents on rural problems to implement the party policy on rural areas. In the meantime, the state adopted many measures to improve agriculture. To begin with, it raised by about one-fourth the purchasing prices of 18 agricultural and subsidiary products, such as grains, cotton, oilseeds, hogs, poultry, and eggs. The increase in purchasing prices for output which exceeded the quota was even greater. The state also reduced or exempted the agricultural taxes for low-income rural communes and production brigades and teams as well as the industrial and commercial taxes for enterprises operated by communes and production brigades and teams. This allowed the peasants, the communes and production brigades and teams to increase their income by more than 9 billion yuan. In addition, the state increased its investments in agriculture from the 10.7 percent of its total investment in capital construction in 1978 to 14.0 percent in 1979.

Faster development in the textile and light industries. To readjust the proportionate development of the light and heavy industries, the state started in 1979 to give "special considerations" to the supply of fuel, motive power, raw materials and other supplies for the textile and light industries, and in addition provided financial support. In 1979, the state allocated much more capital for technical improvements in the textile and light industries than in 1978, and also increased the proportion of textile and light industrial investments in the state's capital construction plan. The banks also increased their loans to the textile and light industries. In addition, the state made available to the textile and light industries a certain amount of foreign exchange for importing raw materials and other supplies, and directed the heavy industry and military industry to produce light industrial products. Thanks to these measures, the light industry showed quick development in the latter part of 1979, there was an increase in textile and light industrial products, and market purchases and sales both improved.

Capital construction front being shortened. In 1979, the state took the job of shortening the capital construction front as an important measure in readjusting the national economy. It resolutely discontinued and postponed the projects which were premature or which were not urgently needed by the state. According to the plan in early 1979, 561 major projects were to be discontinued or postponed. Of these, thanks to a concerted effort, more than 330 have actually been discontinued or postponed.

Some industrial plants which were developed indiscriminately have been converted, amalgamated, closed or suspended. China now has more than 350,000 industrial enterprises. It is impossible to keep all of them adequately supplied with fuel, motive power, raw materials and other supplies. The various localities are now engaging in converting, amalgamating, closing and suspending those enterprises which were developed indiscriminately, which required the consumption of large quantities of raw materials or which suffered losses over a long period of time. According to incomplete statistics, more than 2,000 enterprises belonging to this category were converted, amalgamated, closed or suspended.

The state has improved the living conditions of the people in cities and towns by finding employment for the unemployed, raising the income of workers and building more living quarters for them.

Finance

Since the founding of the People's Republic of China, thanks to the continual development of industrial and agricultural production, the state finance has shown improvement year after year. Both income and expenditures have increased. They have largely been in balance, with a little surplus in income. The state has relied for its financial income mainly on the taxes and profits from state-operated enterprises, which account for over 90 percent of the total income of the state. The government formulates a state budget each year. As a basic state financial plan, it is an important part of the national economic plan. The state budget consists of the central budget and local budgets. The constitution of China provides that the state budget and local budgets are subject to the examination and approval of the people's congresses at the various levels. The state budget is controlled according to the principle of democratic centralism--it is placed under a unified leadership but under the control of authorities at different levels. The policy of "maintaining a balance between incomes and expenditure with a little surplus in income" is followed. The fiscal year runs from 1 January to 31 December.

State budgeted incomes include the incomes of enterprises and other business organizations, industrial and commercial taxes, salt tax, customs duties, agricultural taxes and other incomes. State budgeted expenditures include economic construction expenditures, sociocultural, educational, scientific, and public health expenditures, national defense expenditures, administrative expenditures, and others.

The 1978 state final accounting of incomes and expenditures shows that the total income amounted to 112.111 billion yuan and the total financial expenditure amounted to 111.093 billion yuan, showing a favorable balance of 1.018 billion yuan. Compared to 1977, financial income increased 28.2 percent, and expenditures 31.7 percent.

In 1979, the tasks of state finance were: On the basis of making a great effort to consolidate enterprises and develop production, to further tap potential, open new financial sources, and increase financial income. In light of the readjustment of the national economy, to make rational arrangements for various expenditures, strengthen agriculture and light industry, and strengthen the weaker links in the national economy such as the coal, electric power, oil, transportation and building materials industries. To strengthen cultural, educational, public health, and scientific undertakings. To strengthen national defense and war preparedness. To gradually improve the living conditions of the people. Consolidate financial work, do a good job in controlling financial income and expenditures, uphold the policy of using the amount of income to determine expenditures, and make an effort to strike a balance between income and expenditures. In a resolute, positive and sure-footed manner, embark on reforming the financial control system and the financial systems of enterprises to bring the enthusiasm of central and local enterprises and their workers into full play.

According to the draft 1979 state budget, the total state income was 112 billion yuan, and so was the total state expenditure, of which expenditures for capital construction amounted to 39 billion yuan, that of national defense, 20.23 billion yuan, and that of culture, education, public health, and scientific research 12.08 yuan.

Banking

Since the founding of the People's Republic of China, the Central People's Government has adopted a series of measures to take over the banking organizations of the bureaucratic capitalist system, abolish all the banking prerogatives of imperialism in China, forbid financial speculations, carry out socialist reform of private banks, unify the control and issuance of currency, replace the bogus Jinyuanquan currency with Renminbi, forbid the circulation of foreign currency, and establish a unified and stable socialist currency system and financial and banking system.

Renminbi was first circulated in China in December 1948. Following the basic stabilization of the financial situation in China, to improve and consolidate the currency system, the People's Bank of China started to issue the new Renminbi on 1 March 1955 to replace the old Renminbi which was in larger denominations. The exchange rate between the new and old people's currencies was one to 10,000.

The People's Bank of China is the state bank of the People's Republic of China. It was founded in December 1948. It serves as the central bank for credit loans, settling of accounts, and cash activities, and as the only organization to issue currency. In October 1954, the Construction Bank of China was established to handle appropriations for capital construction for the state. It has branches in the various provinces, municipalities and autonomous regions. The Bank of China was reorganized to specialize in foreign exchange, centralizing the handling of international accounts, international credit, foreign trade, credit, and the purchase and sale of foreign exchange, etc., for the entire country. In addition to these banks, there are also the Agricultural Bank of China, rural credit cooperatives and other credit organizations.

The credit system in China is characterized by the centralized control of credit by banks. All loans must be handled by banks, and all the loans must be issued according to plan and used as stipulated.

Since the founding of the new China, following the continual improvement in the livelihood of the people, the urban and rural areas have continually developed their savings business. Deposits received by the People's Bank are divided into two categories: public deposits and private deposits. All enterprises, agencies, organizations, military units, schools and collective economic units must deposit any cash which is over and above the amounts permitted to be kept on hand in banks. The urban and rural people may deposit their money in banks as personal savings, entirely on a voluntary basis. To promote savings, the Party and state have adopted a correct policy: private savings ownership is protected, savings deposits are voluntary, freedom of withdrawal is guaranteed, savings deposits will bear interest, and confidentiality is kept for savings deposit holders. Since the founding of new China, urban and rural savings deposits have grown continually. In 1979, savings deposits in cities and towns throughout China totaled 20.26 billion yuan, a 30.8 percent increase over 1978, and that in rural areas totaled 7.84 billion yuan, a 40.8 percent increase over 1978.

China has developed its insurance business to a certain extent also. The state instituted the People's Insurance Company of China with branches in many areas at the beginning of the liberation. It conducted extensive insurance business at home and abroad. Later, this business was suspended for a long time, until January 1980 when it began to recover. The policy of domestic insurance in China is to serve the interests of production and of the masses on the basis of voluntary application for insurance by the clients themselves.

[Article by Guo Hongli [6753 1347 7787]]

Industry

Industry in the old China was very backward, with only a few light industry and textile industries in the coastal cities. In the past 30 years since the founding of the new China, however, a relatively complete industrial network has largely been established. An industrial base of heavy and light industries was founded, including machine-building, metallurgical, coal, oil, chemical, electric power, electronic, textile and other industries. China now has more than 6,000 large and medium-size enterprises. In addition, the 50,000-odd rural communes in China have established more than a million small enterprises according to local conditions. During the period 1950 to 1978, China enjoyed an increase in total industrial production value of 13.5 percent each year. Its total industrial production value in 1979 amounted to 459.1 billion yuan, an 8.5 percent increase over 1978, and its light industrial production value amounted to 198 billion yuan, a 9.6 percent increase over 1978, surpassing the rate of increase in heavy industrial production value by 7.7 percent.

After the "gang of four" was smashed, China adopted the policy of readjustment, restructuring, consolidation and improvement in developing its industry and promoted a mass movement for increasing production, practicing economy, increasing income and cutting down expenditures. By 1979, China also adopted the policy of relying both on planning and market conditions in regulating its economy, with greater emphasis on planning. It curtailed some of its capital construction projects, strengthened its textile and light industries, and granted greater autonomy to enterprises, thereby greatly promoting the development of production.

Agriculture

Prior to the founding of the new China, our country's agricultural production was very backward. No progress was made in agriculture for a long time. With the founding of the new China, the Party and government paid great attention to the development of agricultural production, adopting the basic policy of agricultural collectivization, to be followed by mechanization and electrification. The land reform campaign spelled the end of the feudal exploitation type of land ownership. The state confiscated about 700 million mu of land from the landlords and rich peasants, and redistributed it to the more than 300 million peasants who had little or no land. After that, the peasants were directed onto the road to collectivization, organizing themselves into mutual-aid teams, primary cooperatives, advanced cooperatives and, by 1958, into people's communes. At present, China has more than 52,000 people's communes and 2,047 state farms.

China has adopted the following policy in developing its agriculture: Take food grains as the key link in the overall development of agriculture, suitably centralize the control of agricultural production while paying due attention to local factors, and promote at the same time the development of agricultural, forestry, animal husbandry, subsidiary and fishery production.

In 1962, following the promulgation of the "People's Commune Work Regulations (Draft)," the Chinese peasants greatly developed their work enthusiasm, quickly reversing the stagnant situation prevailing in the previous 3 years. Agricultural production was restored and developed. Nevertheless, during the period when Lin Biao and the "gang of four" were riding high, agricultural production development slowed down again. Some areas even suffered a reduction in agricultural production. After the Third Plenum of the 11th CCP Central Committee, the state implemented the two documents on agricultural development issued by the Party Central Committee and the party policy on rural areas, making a concerted effort to quickly develop agricultural production. Much attention was paid to the material well-being of the peasants. In 1979, the state raised the purchasing prices of 18 agricultural and subsidiary products, upheld the private plots for commune members, and permitted them to engage in household subsidiary production and trade in rural marketplaces, thereby bringing the socialist enthusiasm of the broad masses of peasants into full play. As a result, although a relatively serious natural calamity hit China in 1979, the peasants in most areas in China increased their agricultural production and income. The total agricultural production value in 1979 in China was 8.6 percent higher than that of 1978.

Commerce

China's commerce is a socialist commerce established on the basis of socialist public ownership. In this field of work, the state adopted the general policy of "developing the economy and assuring supplies." It organized the circulation of commodities in China in a manner to unite cities with rural areas, industry with agriculture, and producers with consumers.

Commerce in China is mostly state-operated both in cities and rural areas. It conducts more than 90 percent of the commodity retail business in China in terms of business volume. The state has administrative organizations as well as control and operational organs for the enterprises at every level. There is a commercial network covering all cities and towns and industrial, mining, and forest areas. There are supply and marketing cooperatives which have their own control and operational organizations. They are commercial units of the masses established on the basis of voluntary participation, democracy and mutual benefit. Following the development of the socialist revolution and construction and the increase in the accumulation of capital on the part of the supply and marketing cooperatives, these cooperatives have advanced from their previous collective ownership to ownership by the whole people.

The control of commodities is carried out according to the general policy of overall planning and administrative control at different levels. Price control is an integral part of the planned control by the state. The State Bureau of Commodity Prices handles the price control policy, regulates the general price level, and readjust commodity prices, seeing to it that they are in good balance. Under overall planning by the state, the retail prices of the major daily necessities in China have been stable in the main. On many occasions the state has reduced the prices of pharmaceutical products, brought closer the prices of industrial and agricultural products, raised the purchasing prices of agricultural and subsidiary products, and lowered the prices of industrial supplies for agriculture. The difference between industrial and agricultural products today is reduced by more than 40 percent as compared to that of 1952. Price differentials between different localities have been reduced, and the commodity prices in rural markets have also gone down somewhat.

Thanks to the increase in agricultural and industrial production and to the import of some consumer goods in suitable amounts, China enjoyed a brisk and active market in 1979. The total volume of agricultural and subsidiary products purchased by the state amounted to 58.68 billion yuan, exceeding that of 1978 by 27.6 percent. The actual increase amounted only to 4.5 percent, however, if the increase in purchasing prices is discounted. The total volume of industrial products purchased by the state amounted to 140.56 billion yuan, a 9.8 percent increase over 1978. The total volume of retail social commodities amounted to 175.25 billion yuan, a 14.7 percent increase over 1978.

Foreign Trade

After the founding of the People's Republic of China, the state formulated its foreign trade policy according to an overall plan. Arrangements for foreign trade were made according to the national economic plan, and foreign trade was conducted according to the policy of independence and self-determination.

China actively established trade relations with Third World countries on the basis of equality, mutual benefit, the exchange of goods needed by one another, respect to one another's sovereignty, and the needs and capabilities of the states concerned. By 1979, China had established trade relations with more than 130 states and regions of the Third World.

With regard to countries of the Second World, China actively developed trade with them on the basis of equality and mutual benefit, and exchanged its products with them for advanced technical equipment and other supplies needed by China for socialist construction. In 1979, the volume of trade between China and Japan exceeded US$6 billion. Following Japanese Premier Ohira's visit to China, Japan planned to extend a loan of 50 billion yen to China in 1979 to assist in the construction of six projects in China. It also decided to grant most favored nation status to China in customs duties beginning April 1980. In 1979, the total volume of trade between China and the European Common Market amounted to US$5 billion, an increase over 1978 of more than 50 percent.

Since the reestablishment of diplomatic relations between China and the United States on 1 January 1979, trade between the two countries has shown considerable development. In 1979, Sino-U.S. trade amounted to US$2.45 billion, showing an increase over that of 1978 by 147 percent. In 1979, U.S. Vice President Mondale came to China to sign an agreement, offering U.S. technical assistance in developing hydroelectric power in China. On 1 February 1980 when Sino-U.S. Trade Agreement began to take effect, the two countries recognized each other as a most favored nation.

Communications, Postal Service and Telecommunications

Railways. Since the liberation, China has quickly developed its railways. From 1952, China has built more than 30 trunk lines, including the Chengdu-Chongqing and Tianshui-Lanzhou railways. By 1979, China's railway mileage open to traffic was 1.3 times more than that at the time of the liberation, and the freight volume was 18 times greater. Beginning in 1952, China began to build its own steam locomotives. At present, there are more than 30 locomotive and rolling stock plants in China engaging in building steam locomotives, internal combustion locomotives, electric locomotives, large passenger cars, and new passenger car models. In 1979, the total freight volume on railways amounted to 1,094.95 million tons, showing an increase over that of 1978 by 1.9 percent. The total volume of cargo turnover on railways amounted to 558.8 billion ton-kilometers, a 4.8 percent increase over 1978, and the amount of passenger transportation on railways totaled 121.4 billion man-kilometers, an 11.3 percent increase over 1978.

Highways. On the eve of the liberation, there were 80,000 kilometers of highways in China open to traffic. These highways were characterized by their low standards and poor conditions. By the end of 1979, the total mileage of operational highways in China was 890,000 kilometers, more than 11 times that at the founding of the new China. In 1979, the total freight volume on highways amounted to 815.56 million tons, showing a decrease of 4.3 percent as compared to that of 1978; the total volume of goods transported on highways amounted to 26.8 billion ton-kilometers, showing a decrease of 2.2 percent. These decreases were caused by a reduction in business on the part of the transportation departments, as many industrial and commercial enterprises started to transport more goods by themselves. The amount of passenger transportation on highways totaled 60.3 billion man-kilometers, an increase of 15.7 percent over 1978.

Ocean shipping. In the past 30 years, the Chinese ocean shipping fleet has gradually developed from nothing to a major industry. By the end of 1979, the Chinese ocean shipping fleet was composed of more than 400 ships including bulk-load, general cargo, tankers, passenger ships, roll-on roll-off, and container ships totaling more than 7 million tons. They ply the waters of the three great oceans, eastward to Japan and Canada, the United States and Latin America across the Pacific; westward to South and West Asia, Africa and European countries through the Indian Ocean, the Suez, the Mediterranean, and the Atlantic Ocean, sometimes by way of the Cape of Good Hope; southward to Southeast Asia and Oceanian countries, and northward to Korea. The Chinese fleet has visited more than 100 countries and regions, and called on more than 400 ports.

Inland river shipping. In 1949, the Chinese inland river waterways totaled 73,600 kilometers, including 24,200 kilometers of motor vessel navigable waterways. By 1979, the inland river waterways had increased to more than 136,000 kilometers, including more than 79,000 kilometers of motor vessel navigable waterways. The amount of goods handled by inland river shipping accounts for one-fifth of the total amount of goods transported in China. Inland river shipping is one of the most inexpensive means of transportation in China.

Civil aviation. In December 1949, the new China established its Civil Aviation Bureau (now known as Civil Aviation Administration of China). By 1979, after 30 years of construction and development, it had established 158 air routes, linking more than 80 cities in China, totaling about 108,600 kilometers. There are direct flights from all provinces, municipalities and autonomous regions to Beijing. In addition, there are 15 international air routes, totaling 51,300 kilometers. At present, China has entered into aviation agreements with more than 30 countries, and established business or financial relations with more than 100 foreign airline companies. In 1979, the amount of air freight totaled 79,900 tons, a 25.2 percent increase over 1978, and the amount of goods shipped by air totaled 123,400 ton-kilometers, a 27.2 percent increase over 1978. The volume of passengers totaled 3.5 billion man-kilometers, a 25.3 percent increase over 1978.

Ports. Prior to the liberation, the largest ship that could be docked in China was 10,000 tons. After the liberation, China completed the Tianjin New Port (1952), the Zhanjiang Port (1956), the Dalian Nianyuwan Oil Port (for ships of 100,000-ton class), the Qinhuangdao Oil and Coal Wharf, and the Huangpu Oil and Ore Wharf. Since 1973, China has established 42 deep-water berths to accommodate ships of over 10,000 tons, and has expanded and renovated the Shanghai, Huangpu, Dalian, Qinhuangdao and Qingdao ports to improve their mechanized loading and unloading facilities, thus enhancing their ship loading and unloading capacity. In 1979, the coastal ports in China loaded and unloaded a total of 212.57 million tons of cargo, surpassing that of 1978 by 6 percent. At present, many ports are open to foreign trade shipping. The number of foreign ships calling on China's ports totals over 10,000 a year.

Bridges. The old China built very few bridges. There was no bridge spanning the 10,000-li Changjiang, and there was only one highway bridge across the Yellow River, built by a French engineer. At the time of the liberation, the stone-arch bridge at Zhaozhou, built more than 1,300 years ago, was still the bridge with the largest span in China. After liberation, bridge construction developed by leaps and bounds. More than 30 highway bridges were built across the Yellow River. By now, there are about 128,000 highway bridges in China, totaling more than 3.2 million meters. With the exception of some of the bridges in forest areas which were built with timber, over 90 percent of highway bridges in China are of permanent structure.

Postal and telecommunications services. China has greatly developed its postal and telecommunications services in the past 30 years. The postal and telecommunications network now covers all the urban and rural areas in China. Telecommunications is advancing from relatively primitive to more sophisticated operations. The postal service has also advanced from backward and clumsy manual labor to mechanization and automation. With the successful development of coaxial cable, 1,800-channel carrier-wave systems, 960 channel microwave telecommunications systems, and the successful study and installation of such telecommunications facilities as fascimile transmitters, data transmitters, automatic switchboards for long-distance telephone and Chinese character decoders, the Chinese postal and telecommunications services have taken on a new look.

Since 1969, China has established a microwave telecommunications network having 600 microwave electronic-tube channels and 960 transistor channels for transmitting black-and-white as well as color television programs, and also providing telephone services between Beijing and 26 provinces, municipalities and autonomous regions. In addition, newspaper facsimile transmission services have been established between Beijing and 9 other cities including Chengdu, and one-way facsimile transmission service has been established from Beijing to Guangzhou.

Chinese postal routes total 4,812,000 kilometers, of which 30 percent, or a little over 1.4 million kilometers, is covered by motorized service. At present, China has about 50,000 postal and telecommunications offices, of which about 30,000 are in rural areas. About 60 percent of the communes in China now have their own postal and telecommunications offices. Some 4.26 million kilometers of the postal routes are in rural areas. China's rural telephone lines total 1.8 million kilometers. Of the Chinese communes, 99.8 percent have direct postal service. Postal and telecommunications services have shown tremendous development in China. The total business volume in 1979 amounted to 1.255 billion yuan, surpassing that of 1978 by 7.7 percent. Specifically, the increase in the volume of postal business amounted to 8.6 percent, that of telegraph, 5.9 percent, and that of long-distance telephone, 10.8 percent.

China has established direct postal services with more than 110 countries and regions, and direct telecommunications services with 47 countries and regions. China now has three satellite earth stations to maintain contacts with many countries. A 480-channel submarine cable was installed between China and Japan, starting communications service on 25 October 1976. A 16-line radio telephone service has been established between Peking, Shanghai and Tokyo.

[Article by Zhang Minliang]

International Trade and Economic Cooperation

Upon its founding, the People's Republic of China immediately abolished all the imperialist prerogatives in China, regained control over its customs operations, and adopted a policy to control its foreign trade. The state formulated its foreign trade policy according to an overall plan, so that foreign trade was carried out according to the national economic plan, on the basis of maintaining independence, keeping the initiative in our own hands, and conducting foreign trade according to the basic principles of equality, mutual benefit, and the exchange of goods according to each other's needs. Just as pointed out by Mao Zedong, we should "rely mainly on our own efforts while making external assistance subsidiary." Accordingly, on the basis of relying mainly on our own efforts, we may import some necessary advanced technology and equipment to speed up the development of our national economy.

In 1964, on behalf of the Chinese Government, Premier Zhou Enlai announced the 8-point Chinese foreign aid principle as follows: (1) The Chinese Government offers foreign aid consistently on the basis of equality and mutual benefit. It has never taken such aid as one-sided favor, but considers it as a mutual thing. (2) In providing foreign aid, the Chinese Government strictly respects the sovereignty of the recipient country, and extends aid with no strings attached and without any demands for prerogatives. (3) The Chinese Government offers economic aid in the form of interest-free or low-interest loans. Repayments for such loans may be prolonged to reduce the burdens of the recipient countries. (4) In offering foreign aid, the Chinese Government does not aim at foreign dependence on China, but rather at helping the recipient countries step on the road to independence through their own efforts and through development of their economy independently. (5) The Chinese Government tries its utmost to confine the projects with which it helps the recipient countries to those which require small investments but yield fast results to enable these countries to increase their income and accumulate wealth. (6) The Chinese Government offers its equipment and supplies of the best quality at negotiated prices according to international market prices. If the equipment and supplies fall short of the specifications and quality agreed on, the Chinese Government guarantees their replacement. (7) In offering any type of technical aid, the Chinese Government assures that the recipient countries' personnel will fully master the technology required to benefit from such aid. (8) The experts sent to the recipient countries by the Chinese Government will receive the same material benefits as the specialists of the recipient country, and are not allowed any special requests or benefits.

China has actively developed its foreign trade according to its foreign trade policy. From its founding to 1979, China had established trade relations with more than 170 countries and regions, and had signed a trade agreement with the European Common Market.

Beginning in 1957, China has held Chinese export commodity Trade Fairs in Guangzhou each spring and autumn. By 1979, 46 such trade fairs had been held. The number of people participating in such fairs, including foreign friends, overseas Chinese, Taiwan compatriots living in foreign countries, and compatriots in Hong Kong and Macao has increased from the 1,200-odd people from a little over 20 countries and regions at the first fair to more than 24,000 from more than 100 countries and regions. The variety of goods on display and the volume of trade also showed tremendous increase. Since its founding to 1978, the New China held almost [illegible] economic and trade exhibitions in more than 90 countries in Asia, Africa, Europe, America and Oceania. In the meantime, it also accommodated more than 110 consolidated and specialized exhibitions in China by more than 20 foreign countries. In 1978, the first farm machine exhibition was held in China under the sponsorship of 12 countries. These activities greatly promoted the development of foreign trade and economic cooperation between China and other countries in the world. In his "Government Work Report" delivered to the Second Session of the Fifth National People's Congress in June 1979, Premier Hua Guofeng said that in the new Long March to realize the four modernizations, China needs "a great development in its foreign trade."

Readjustment and Development of the Chinese National Economy

In early 1979, based on the development of the national economy and existing problems, the party and government decided that after shifting the focus of work in the nation to the realization of socialist modernization, concentrated efforts be made in the next 3 years to readjust, restructure, consolidate and improve the national economy. The readjustment calls for readjusting the proportionate development of the various branches of the national economy which was undermined by Lin Biao and the "gang of four," so that the national economy can be developed in a harmonious manner, and so that a rational ratio will be maintained between accumulation and consumption. The restructuring calls for restructuring the entire economic management system step by step to bring the superiority of the socialist system into full play. The consolidation calls for properly reorganizing existing enterprises, particularly those which are suffering from bad management, so that all the enterprises will be on the right track in all their operations. The improvement calls for substantially raising production, technological, and management levels.

Through the implementation of this policy, remarkable successes were achieved in 1979.

1. Agriculture was realistically strengthened. In the implementation of the two documents, i.e. "Decision of the CCP Central Committee on Certain Problems Concerning Speeding up the Development of Agriculture" and "Work Regulations Concerning Rural People's Communes (Trial Draft)," sincere efforts were made to carry out the Party policy on rural economy and raise the purchase prices of agricultural and subsidiary products to bring about unprecedented prosperity in the vast rural areas in China. The state spent about 10.8 billion yuan to raise the purchase prices of agricultural and subsidiary products. This upward readjustment in prices was the largest since the founding of the New China. In addition, the agricultural taxes

of some areas were reduced or exempted, and the business taxes of all enterprises operated by communes and production brigades and teams were exempted, costing the state over one billion yuan. In the meantime, the state increased its investments in agriculture, thereby increasing the proportion of agricultural investment in capital construction investment as compared to that of 1978, and both the central and local authorities spent more money on agriculture than before. Furthermore, all industries and trades also increased their support to agriculture. All these factors contributed to the development of tremendous enthusiasm in agriculture by the broad masses of peasants, thus bringing about an overall increase in agricultural production. In 1979, the total agricultural output value amounted to 158.4 billion yuan, an increase of 8.6 percent over that of 1978, a bumper harvest year. Grain production totaled 664.23 billion jin, an increase of 54.7 billion jin over that of 1978; cotton totaled 44.14 million piculs, an increase of more than 0.8 million piculs; oil seeds, 128.7 million piculs, an increase of 24.34 million piculs; and the number of live hogs, was 319.705 million, an increase of 18.415 million. The output of sheep, poultry, eggs, and silkworm cocoons also increased to varying degrees.

2. The proportional relationships within the industrial sector began to improve, and there were initial successes in the reorganization of enterprises. In 1979, the central and local authorities adopted many measures to speed up the development of the textile and light industries, such as increasing their investments, providing more bank loans, supplying fuel and power on a priority basis, and importing quantities of raw and processed materials. The rate of growth in the textile and light industries throughout the nation was 9.6 percent, surpassing the 7.7 percent growth of heavy industry. The growth of the chemical fertilizer industry and other industries in support of agriculture also picked up speed. Initial successes were achieved in the readjustment and consolidation of industrial enterprises. Incomplete statistics compiled in 21 provinces, municipalities, and autonomous regions show that they closed, suspended, merged and converted 3,600 enterprises which were characterized by high consumption of raw materials, had inferior products or products with low consumer demand, and operated at a loss over a long period of time. Thanks to these readjustments and consolidations, industrial production in China began to develop in a realistic and steady manner. In 1979, the gross value of industrial output in China amounted to 459.1 billion yuan, an increase over that of 1978 by 8.5 percent. The output of 89 of the 100 major industrial products overfulfilled state plans ahead of schedule. Steel production amounted to 34.48 million tons, an increase of 2.7 million tons over that of 1978; power generation, 281.95 billion kilowatt hours, an increase of 25.35 billion kilowatt hours; chemical fertilizer (calculated on the basis of 100 percent effective components) 10.654 million tons, an increase of 1.964 million tons; and cotton yarn, 2.63 million tons, an increase of 0.248 million tons. There was an overall improvement in the economic and technical indicators in industrial production. According to statistics, the quality indicators showed improvement in 30 major products in the metallurgical, coal, petroleum, chemical, building material, textile, and light industries. Ten of the 11 major power grids in China achieved a frequency stability rate of over 99 percent. In the steel industry, the production of five steel products in short supply in China, including small shaped-steel products, wire rods, thin plates, welded steel pipe and high-grade shaped steel, accounted for 61.6 percent of the total output of steel products, a 22 percent increase over 1978. In the machine building industry, enterprises of the First Ministry of Machine Building Industry fulfilled plans for the trial production of 856 new products. This was a 12.5 percent increase over 1978, and the best showing in more than 10 years.

Remarkable successes were achieved in energy conservation. In 1979, some 23 million tons of coal, more than 1.5 million tons of fuel oil, and more than 6 billion kilowatt hours of electricity were saved through conservation. Although the increase in coal, petroleum and hydroelectric power amounted only to 3 percent in 1979, the growth rate of industrial production as a whole exceeded 8.5 percent. Outstanding results were also achieved in the development of communications, transportation, postal and telecommunications services. State plans for railway and waterway freight volumes were overfulfilled.

3. The capital construction front was shortened, and the results of investments improved. In 1979, the proportionate distribution of investments was suitably readjusted, so that more investments were made in agriculture and the textile and light industries. At the same time, more investments were made in nonproductive construction projects, such as workers' housing, municipal public utilities, and cultural, educational and public health construction projects. This improved the relationship between "flesh" and "bones." The investments in nonproductive construction projects accounted for 27 percent of the total investments of the state, topping that of the past 20 years since 1958. In 1979, 348 large and medium-sized projects were suspended or postponed in China. This enabled the state to focus its limited financial and material resources more on key projects and urgent projects, thereby improving the results of its investments. In 1979, 128 large and medium-size projects were completed, 29 more than in 1978. The proportion of capital construction investment represented by new fixed assets rose from 74.3 percent in 1978 to 83.7 percent. Because of the reduction in capital construction investment, plus the suitable reduction in accumulated funds in other fields, the rate of accumulation (that is, the ratio of accumulated funds to national income) dropped a little from the 36.6 percent of 1978.

4. The supply of commodities increased substantially, and market conditions in both urban and rural areas became more active. In 1979, commercial departments purchased commodities totaling 199.24 billion yuan, a 14.5 percent increase over 1978. The retail volume of social commodities totaled 175.25 billion yuan, an increase of 14.7 percent over 1978, or a real increase of 12.4 percent if price changes are taken into account. This was the largest increase in 20 years. In many medium-to-large cities, pork was obtainable in abundant quantities, and the supply of other non-staple food items also improved. More everyday industrial products were supplied to rural areas.

5. Economic and technical exchanges with foreign countries were carried out in many forms, and import-export trade grew substantially. In 1979, the volume of foreign trade totaled 45.5 billion yuan, an increase of 28 percent over 1978, of which the volume of exports totaled 21.2 billion yuan, an increase of 26.3 percent. During 1979, new avenues were opened in obtaining foreign investments and importing foreign technology, enabling us to gain some experience in this field.

6. New developments were achieved in science, education, culture, public health and sports. In 1979, successes were achieved in 2,790 major scientific and technological research projects, and 42 inventions were approved by the state. In addition, basic theoretical research reached advanced international levels in certain fields. The total enrollment of students in institutions of higher learning reached 1.02 million, an increase over 1978 of 164,000 and the highest level

ever. The total enrollment of students taught through television amounted to 280,000, and that in factory-operated colleges and spare-time colleges, 580,000. There were also developments in the fields of culture, public health and sports.

7. Some improvements were achieved in urban and rural living standards. In 1979, each peasant averaged an income of 83.4 yuan from the collective, an increase of 9.4 yuan over 1978. During 1979, the number of unemployed youths and other personnel placed in jobs in cities and towns nationwide, and the graduates from colleges and vocational schools given assignments by the state came to 9.026 million. Beginning in November 1979, more than 40 percent of the workers in China had increases in their wage scales or readjustments in their wage categories. Even with the labor force expanding noticeably, there was still a substantial increase in the average pay of personnel and workers. In 1979, the average pay of personnel and workers in the employment of units under ownership of the whole people amounted to 705 yuan, an increase over 1978 of 61 yuan. Further, some 62.56 million square meters of new living quarters were built for personnel and workers. This was the most housing built in any year in China's history, and enabled 5 million people to move into new living quarters.

8. With regard to the economic management system, some studies and reforms were carried out. Thousands of different enterprises engaged in trial runs to expand their autonomy, in which they were allowed to retain a percentage of their profits, increase the rate of depreciation of their fixed assets, expand their production, and regulate their production mainly by planning but also by market conditions. In foreign trade, a plan was tried whereby the enterprises concerned could retain a portion of their foreign exchange, and in capital construction, funds were obtained by units from bank loans on trial basis rather than from allocations by the state. Although these reforms were preliminary and partial, they yielded remarkable results and provided useful experiences for carrying out overall reform in the future.

The national economic readjustment carried out in 1979 yielded good results in many fields. In some cases, the results were better than anticipated. Naturally, the readjustment of the national economy is an onerous and complex task, and there are many problems to be solved. For instance, the production plans for cotton, beets and aquatic products for 1979 were not fulfilled, the readjustment and reorganization of industrial enterprises were carried out too slowly, there was no marked change in the low yield of investments some of the projects which should have been suspended or postponed were still being built, the reform of economic management system just started was in need of further progress, some localities and units increased their commodity prices arbitrarily or in a disguised form and thereby increased the burden of the masses in their daily lives, and too many bonuses were issued on much too egalitarian a basis. The Party and government are adopting measures to sincerely solve these problems in order to do a good job in fulfilling the tasks concerning the readjustment, restructuring, consolidation and improvement of the national economy.

Gross Industrial and Agricultural Output Value in China
(in billion yuan)

Year	Gross ind. & agri. output value	Gross agricultural output value	Gross industrial output value	Within gross industrial output value: Light ind. output value	Within gross industrial output value: Heavy ind. output value
	(Calculated in terms of 1952 constant yuan)				
1949	46.6	32.6	14.0	10.3	3.7

	(Calculated in terms of 1970 constant yuan)				
1978	569.0	145.9	423.1	180.6	242.5
1979	617.5	158.4	459.1	198.0	261.1

[Article by Xu Jingan [1776 2529 1344]]

Reform of the Planned Management System

The planned management system came into being gradually in the course of the First Five-Year Plan. This system was characterized by stress on a high degree of centralization and unified leadership of the national economy. Under it, plans concerning the output of major agricultural and industrial products, the size of capital construction investment and most of the projects, allocation of the major means of production, income and expenditures by central and local financial authorities, number of new workers and total wage expenditures, purchase price and allocation of major consumer goods, prices for major industrial and agricultural products, etc., were all decided by the state and passed on to the local authorities and enterprises in the form of directives. Following the development of the national economy, this system became more and more detrimental to the development of enthusiasm on the part of the workers of the various localities, and thus hindered the development of productive forces.

In 1958, the planning system underwent some major reform according to the principle of "unified planning and level-by-level management," granting greater economic management authority to the provinces, municipalities and autonomous regions. Under this reform, once the fulfillment of state-assigned tasks was assured, the local authorities had the power to make overall arrangements for local construction and production, regulate and utilize local supplies, and make use of local funds. At the same time, the various provinces, municipalities and autonomous regions were responsible for bringing about a comprehensive balance in the plans of central and local enterprises within their jurisdictions. Subsequently, more reforms on the planned management system were carried out in 1961, 1964 and 1970. However, post-1958 reforms dealt primarily with the division of power between central and local authorities, without making any important change in the relationship between the state and enterprises. The state still exercised centralized power and controlled enterprises in a stifling manner. Enterprises lacked the necessary autonomy. The state determined what and how much each enterprise would produce, supply it with materials for production according to an overall plan, purchase all its products through state-operated supply units and commercial units, collect almost all its profits, approve its rebuilding and expansion, and allocate its investment funds. Furthermore, in carrying out planned management, the state seldom adopted economic measures or took advantage of economic organizations to bring the market and the law of value into full play. Obviously, without radically changing this planned management system which relied mainly on administrative organizations and measures for control, and without changing the financial system of complete control over all income and expenditures of enterprises, or the system of monopoly purchase and sales of commodities, it was impossible for the national economy to develop continuously at a sustained high speed.

After the downfall of the "gang of four," the CCP Central Committee and the State Council placed the overall reform of the economic management system on their agenda. They proposed changes in the guiding principles of the economic management system, namely, a combination of planned regulation and coordinating the system of market regulation, with the former playing the dominant role and the latter being given full play. Accordingly, the State Economic Commission, the Ministry of Finance, and the various provinces, municipalities and autonomous regions selected a number of enterprises beginning in 1979, carry out expanded autonomy on a trial basis. At the same time to, some changes were made in certain aspects of the planned management system. For instance, as long as an enterprise could assure the fulfillment of the state plan and its goods supply contracts, it could engage in the production of products of popular demand with its remaining fuel, power and raw materials according to the needs for production, construction and the needs of the market, and if it had surplus productive capacity it was permitted to engage in cooperation with other enterprises and in processing products supplied by customers. As for goods circulation, in addition to the method in which goods were allocated by the state, an enterprise was permitted to purchase needed supplies through contracts or through the exchange of supplies with other enterprises. After fulfilling state-assigned plans and goods supply contracts, if an enterprise had surplus products or new products produced on trial basis, it was permitted to market them through its own sales department or through other commercial or supply units. In the field of distribution, an enterprise could retain a certain percentage of its profits according to the ratio set by the state and use it for developing production, improving collective welfare, and issuing bonuses to the workers and personnel. These measures were the initial steps toward the reform of the planned management system. They would be improved step by step in the course of experimentation, so that the planned management system would be more and more in conformation with the objective laws of economics.

The Financial and Economic Commission of the State Council Sponsored Large-scale Economic Problem Study Activities

In late June 1979, the Financial and Economic Commission of the State Council convened a meeting of the responsible members of financial and economic departments and economic research institutions of the central government to arrange for carrying out the largest economic study and research campaign since the founding of the New China. This campaign aimed at directing the comrades who were engaged in practical and theoretical work to join hands in carrying out an overall and detailed study of the economic situation in China and submit their views based on systematically organized data for the reference of related authorities in making decisions on important issues, to pave the way for doing a good job in readjusting the national economy and carrying out a total reform of the economic system. After the meeting, the participants organized themselves into four groups: the economic system reform study group, the economic structure study group, the foreign technology adoption group, and the economic theory and method study group. Each group had a number of investigation and study units. The various industrial communications, financial, trade, agricultural, forestry and water conservancy departments and the various commissions of the State Council also established economic study teams headed by their responsible members to investigate and study existing problems in their own units.

The economic system reform study group aimed at formulating an economic system reform plan which was suitable for China and whose methods were thoroughgoing and could be applied step by step. In 1979, that group held many symposiums in which the participants drafted their "preliminary views on a general concept for economic system reform." In late 1979, members of the group visited Shanghai, Beijing, Tianjin, Sichuan, Liaoning and many other places to solicit views on this general concept and carry out investigations and study. In the course of formulating the general concept, the members also studied the orientation of the economic system reform, its initial steps, its main contents, and certain theoretical problems, such as the limitation to the extent of autonomy to be granted enterprises, the authority and responsibility problem arising from the practice of autonomy, the reliance on planned vs market regulation, and the relationship between administrative and economic measures in carrying out economic management.

The economic structure study group started to make preparations in August 1979 for carrying out a large-scale economic study. It convened 16 meetings of various sizes to hear reports by each of the departments and commissions on their economic structures; the changes, present conditions and the advantages and shortcomings of these structures; and the necessary conditions and methods for reforming unsound economic structures. In addition, the group also sponsored more than 30 symposiums to discuss existing problems in the economic structure in China, the factors contributing to unsound economic structures, and the ideas to reform them. Through this course of study, the group realized that in studying the overall economic structure in China, greater attention should be paid to the relationships between agriculture, the light industry and heavy industry, and between accumulation and consumption, with particular attention to the work of analyzing industrial structures. In each province and municipality, attention should be paid to the ways and means to fully develop local potential in the national economic structure. On the basis of these preparations, the economic structure study group carried out economic investigations in Jiangsu, Shanghai, Sichuan, Heilongjiang, Liaoning, Guangdong and Shanxi, and came forward with 26 investigation reports. After that, the group embarked on the work of analyzing and summing up the history, the present conditions and the future of the Chinese economic structure. In 1980, members of the group will participate in the investigation and research work for formulating a long-term plan for the development of the Chinese national economy under the sponsorship of the State Planning Commission.

The foreign technology adoption study group first held meetings with members of industrial, communications, national defense, capital construction, agricultural, forestry, financial, and trade departments and the State Planning Commission and the State Scientific and Technological Commission to study their adoption of foreign technology. It also asked the foreign trade authorities to brief its members on Chinese export trade and the problems and prevailing conditions concerning the import of foreign technology. The study group drafted a questionnaire, covering problems concerning transnational corporations, foreign investments, joint ventures, the adoption of foreign technology, and the expansion of exports. It has written a number of study reports.

The economic theory and method study group was divided into two groups: the theory study group and the method study group. In 1979, they sponsored a series of seven forums on foreign economics. The theory study group also convened a series of symposiums with instructors of institutions of higher learning, economic research workers and economic department officials to study a number of important theoretical problems which had come up in their researches. In addition, it also sponsored 10 symposiums in 1979 on economic theoretical problems concerning urban collective ownership. In early January 1980, it convened at Shenyang the first national urban collective ownership economic theoretical symposium, and a rural collective ownership economic theoretical problem symposium was convened by it in October 1979. Beginning in November 1979, the theory study group started a biweekly symposium to discuss state ownership economic theoretical problems, which continued until the spring of 1980. The method study group sponsored a planning methodology symposium, and formed a statistical methodology team, an accounting methodology team and a technical economic methodology team to study problems in these fields.

State-operated Economy

The state-operated economy in China is a socialist economy under ownership of the whole people, occupying a leading position in the national economy of China. In 1949, the production value of state-operated industries accounted for 26.3 percent of the gross value of industrial output in China. The state-operated economy accounted for 97 percent of the output of steel in China, 92 percent of pig iron, 68 percent of raw coal, 58 percent of electric power, and 49 percent of cotton yarn. By 1950, the state-operated economy accounted for 6.9 percent of the total socialist commodity retail value. At the same time, the state opened a number of large-scale state farms in Xinjiang, Heilongjiang, Hainan Island and Zhanjiang Peninsula. The establishment of the state-operated economy was an important factor enabling the national economy of the New China to recover and take a turn for the better quickly. It constituted the material foundation for the successful completion of the socialist reform of agriculture, handicraft industry and capitalist industry and commerce. In the past 30 years, thanks to the gradual transformation of private industry and commerce to enterprises of public ownership and also thanks to the planned rebuilding and expansion of old enterprises and the erection of many new enterprises by the state, the state-operated economy has shown great development. In 1978, the fixed assets of state-operated enterprises were 17.6 times greater than in 1952. In 1979, the number of personnel and workers of units under the ownership of the whole people totaled 76.93 million, an increase of 8.6 times over that of 1949. The proportion of state-operated economy enterprises in the entire national economy continued to grow. By 1979, the output value of state-operated industry accounted for 81 percent of the gross value of industrial output in China, and the state-operated commerce retail value accounted for 82.7 percent of the total socialist commodity retail value in China. The financial income provided by state-operated economic enterprises increased from 33.4 percent of the total income of the state in 1950 to 86.1 percent in 1979.

Over a long period of time, due to the fact that the state controlled all the income and expenditures of enterprises and purchased and marketed all their products, and exercised too much, too detailed, and too rigid control over them, the enterprises had no authority to improve their production management, and there was no incentive for their personnel to improve economic results. To change this, the state decided in 1979 to adopt positive steps to reform the management system of state-operated enterprises. Essentially, the reform was to let enterprises enjoy greater autonomy in their production, marketing, financial affairs and labor management within the framework of the state plan, and allow them to retain a fixed percentage of their profits and adopt the bonus system, thereby linking the success or failure of the operations of the enterprises to the incomes of the enterprises and their personnel and workers. This reform was carried out among a number of the enterprises on trial basis with remarkable results in 1979.

Agricultural Collective Economy

The agricultural collective economy was generally formed and developed through the following stages: from mutual-aid teams to elementary agricultural producers' cooperatives to advanced agricultural producers' cooperatives and then to the people's communes. By the end of 1956, in the surging agricultural cooperative campaign, the agricultural economy in China had completed its transition from an individual economy to a collective economy, and by the end of 1958, the people's communalization was completed. In 1979, there were a little over 52,000 rural people's communes in China, embracing more than 170 million households composed of more than 800 million people, including more than 300 million laborers.

The agricultural collective economy in China developed through a course of gradual growth and improvement, and it occupies a very important position in the entire national agricultural economy. Large-scale capital construction was carried out in China after the completion of the transformation to agricultural cooperatives and communalization. The irrigated acreage in China increased from the 400-odd million mu in 1957 to 700 million mu in 1979. More and more farm machines were used. By 1979, the people's commune collective economy had almost 600,000 large and medium-sized tractors, more than 5 million motor-driven irrigation units, and more than 60,000 trucks. Some of the more advanced people's commune in the suburbs of large and medium-sized cities had basically achieved mechanized farming. Thanks to improvements in production conditions and in management, the people's commune collective economy made great strides, and with the development of agriculture, they could contribute more and more to the socialist construction of the state. In 1979, over 90 percent of the grain, cotton, oilseeds and other principal agricultural products purchased by the state were provided by the people's commune collective economy. Following the consolidation and development of the collective economy, members of the people's communes gradually improved their standards of living. In 1979, each commune member averaged 83.4 yuan in income from the collective to which he belonged.

The rural people's commune in China is a socialist economic organization under the collective ownership of the laboring masses engaging in agricultural, forestry, animal husbandry, subsidiary and fishery production, and combining agriculture with industry and commerce in its operations. The basic task of a rural people's commune is to follow the line, principles and policies of the party and government to continually consolidate and develop the socialist collective economy, centering on rural production and construction, and gradually improve and raise the material and cultural livelihood of the commune members on the basis of the development of production. In the meantime, the people's commune should supply more grain, industrial raw materials and other agricultural and subsidiary products in support of the socialist economic construction of the state.

The policy of agricultural production by the people's commune is to achieve overall development, taking food grain as the key link; develop production according to local conditions, have an appropriate degree of centralization, pay equal attention to the development of agricultural, forestry, animal husbandry, subsidiary and fishery production with emphasis on different areas of production in different regions. In food-grain producing areas, the main efforts should be devoted to grain production, with suitable arrangements for the production of economic crops as well as forestry, animal husbandry, subsidiary and fishery production. In forest areas, pastoral areas and fishing areas, the main efforts should be on forestry, animal husbandry and fishery production, respectively. Economic crop areas should engage mainly in the cultivation of economic crops. Suburban areas should devote their main efforts to the production of vegetables, fruits, livestock, poultry and aquatic products. While making great efforts to develop agricultural production, the people's commune collective economy should also develop, according to local resources and social needs, processing industry for agricultural and subsidiary products as well as the mining, construction, farm-machine, and transportation industries to advance the interests of agricultural production, the people's livelihood, large industries and export trade.

The people's commune collective economy practices the socialist principle of distribution, "from each according to his ability, and to each according to his work." As long as the development of the collective economy is not adversely affected, it is permissible for commune members to farm their small private plots and engage in household subsidiary production. The people's commune practices the three-level administrative system, i.e. the means of production are owned at the commune level, the production brigade level and the production team level, with the production team as the basic accounting unit. Under the premises that they uphold the socialist orientation and are guided by the state plan, the collective economic units of a people's commune have the authority to carry out their own operations, cultivate crops according to local and seasonal conditions, adopt measures for increasing production, determine their own management methods, distribute their own products and cash income, and reject the unwise directives of any leading organ or leading individual. All major issues involving a collective economic unit should be determined by its membership in general meetings in commune congresses.

[Article by Zhuang Qidong [5445 0796 2639]]

Urban Collective Ownership Economy

The urban collective ownership economy is an integral part of the Chinese socialist economy. It occupies an important position in the entire national economy, and is playing a more and more important role. In 1979, the total number of workers of the urban collective ownership economy accounted for 22.8 percent of the total number of workers in China, its number of industrial enterprises accounted for 28.1 percent of the total number of industrial enterprises in China, and its output value was 13.9 percent of the gross industrial output value in China. It accumulated some 10 billion yuan for the state, and its business volume accounted for a great percentage in the total retail sales volume and the total foreign trade volume in China. At present, the urban collective ownership economy deals mostly with industry, but also with construction, agriculture, forestry, animal husbandry, subsidiary production, fishery, communications, transportation, commerce, restaurants, service industry, culture, education, and public health. Its enterprises and business units are now distributed in all branches of the national economy.

The urban collective ownership economy has developed in China in the following four stages, giving rise to four basic types of economy.

In mid-1950s, in the course of the socialist reform of the handicraft industry, handicraft producer mutual-aid teams and cooperatives were established. By now, most of them have been developed into enterprises or cooperative plants under ownership of the whole people, becoming the mainstay of the second light industry in China.

In the late 1950s, the urban people started to establish neighborhood factories and production teams with funds raised by themselves. By the end of 1979, the total number of industrial enterprises under urban neighborhood collective ownership amounted to 36,412, with a total value of production of 7.87 billion yuan.

In the late 1960s, government organizations, educational institutions, PLA units, and industrial plants started to establish household factories operated by the dependents of their members. By the end of 1979, there were 6,766 such household factories, with a gross output value of 1.3 billion yuan.

In 1979, the educated young people and other urban people started to establish urban producer service cooperatives and other types of neighborhood enterprises. By the end of 1979, the number of personnel and workers of the enterprises under urban collective ownership totaled 22.735 million, the number of such enterprises totaled 99,679, with a gross output value of 63.72 billion yuan. Compared to that of 1978, the number of personnel and workers of enterprises under urban collective ownership showed an increase of 11.0 percent, and the gross output value of these enterprises showed an increase of 5.8 percent.

1979 was characterized by the coordination of the development of the urban collective ownership economy in with the work of finding jobs for the unemployed young people in urban areas. In 1979, the enterprises and business units under urban collective ownership nationwide employed 6,308,000 or 75 percent, of the unemployed young people (of whom 2,090,000 were temporary employees) in urban areas.

In 1979, the number of commercial units, restaurants and service units and their personnel and workers showed tremendous increases. This greatly improved the living conditions of the urban people and changed the irrational structure of the urban economy in China. By the end of 1979, the number of personnel and workers of retail shops, restaurants and service units under urban collective ownership in China totaled 2,594,000, a 22.8 percent increase over 1978.

In 1979, the urban collective ownership economy played an important role in advancing the interests of foreign trade. The foreign exchange earned from the export of products of the second light industry produced mainly by the industrial enterprises under urban collective ownership totaled US$2.35 billion, a 40.7 percent increase over 1978.

At present, the CCP Central Committee is embarking on formulating policy provisions governing urban collective ownership industries to facilitate greater and faster development of the urban collective ownership economy in the 1980's.

Rural Commune Household Subsidiary Production

Rural commune household subsidiary production is a type of small-scale production engaged in by rural people's commune members after fulfilling their collective labor assignments. This type of production is done by such members during their spare time and during the slack season in agricultural production, tapping the labor potential of their households, taking full advantage of their individual skills, and using the means of production belonging to the collective or themselves. This kind of production is subordinate to the collective economy and complementary to the socialist economy. It also has some of the characteristics of an individual economy and is an important aspect of the economic activities of the commune households.

The party and government has encouraged and supported the household subsidiary production by commune members, according to their long-term economic policy. At the Third Plenum of the 11th CCP Central Committee, it was approved in principle the "Rural People's Commune Work Regulations (Trial Draft)" which provides that, "The household subsidiary production of people's commune members is a necessary supplement to the socialist economy. As long as the development of the collective economy is not adversely affected, the commune members have the right to engage in household subsidiary production without unreasonable interference from any unit or individual." The commune member household subsidiary production is mainly done in the following ways: (1) Cultivate the private plots assigned by the collective (The total acreage of private plots generally accounts for from 5 to 7 percent of the cultivated acreage of the production team concerned.) In pastoral and mountainous areas, some private animals are allowed. (2) Raise such livestock or poultry as pigs, sheep, rabbits, chickens, ducks, and geese. Where practical, commune households may also raise milk cows or beef cattle. (3) Engage in such subsidiary production as matting, embroidery, wild herb collection, fishery, hunting, sericulture and bee-keeping. (4) Raise fruit trees and bamboo around homes.

With agricultural production in China still not at a high level, the commune household subsidiary production can play an important role toward developing the rural economy and increasing the income of commune members. It is beneficial to the development of agricultural production, accounting for one-fifth of the total value of agricultural production in China. It is beneficial to increasing the living standards of the commune members, accounting for one-fourth of the net income of the commune members. It is beneficial to the socialist economic construction of the state, accounting for 90 percent of the pigs, poultry, eggs and other animal by-products purchased by the state. It is beneficial to the rural economy, providing most of the commodities on sale at rural marketplaces and fairs. It is also beneficial to the livelihood of the commune members, enabling the commune members to become self-supporting in livelihood. From this it can be seen that the active development of commune household subsidiary production in the meantime with the development of the collective economy will benefit the state, the collectives and the commune members alike. For some time to come, commune household subsidiary production will most assuredly continue to develop along with the development of the collective economy, although some changes may occur with regard to the makeup of commune household subsidiary production and its place in the rural economy.

Shenzhen and Zhuhai Special Export Zones

Shenzhen and Zhuhai municipalities are adjacent to Hong Kong and Macao, giving them many advantages in producing exportable products, processing products supplied by customers, and engaging in assembling items. The Chinese government decided to establish Shenzhen and Zhuhai as two special export zones on a trial basis, hoping to develop these two municipalities, beginning in 1979, into advanced agricultural-industrial export commodity producing bases in 3 to 5 years, and into attractive sight-seeing spots for tourists from Hong Kong and Macao. The special export zones are controlled under the premise of upholding Chinese sovereignty, enforcing Chinese laws and decrees, practicing Chinese foreign exchange and customs control, so that a number of special policies and flexible measures can be applied. In these special zones, it is permissible for overseas Chinese, Hong Kong and Macao merchants, and foreign industrialists and merchants to make investments and establish plants. It is also permissible for them to establish joint ventures to operate enterprises or tourist facilities. Foreign investments are under the protection of Chinese law. The profits of foreign investments may be remitted to foreign countries according to established rules and regulations, after all taxes are paid. A system of preferential tariffs is applied to the imported goods and exported commodities for and from the special zones. During the period 1979 to 1981, the taxes and profits obtained in the special zones will not be turned over to the state, but used to repay loans and to develop the various undertakings there. To do a good job in establishing Shenzhen and Zhuhai special zones, Guangdong authorities are doing the following: (1) formulating specific management rules and regulations governing the special export zones and (2) formulating the overall construction plans for the two municipalities, including the establishment of bases for exporting fresh and live products, and the construction of processing enterprises for export, hotels, restaurants, department stores, municipal highway facilities, and electric power stations. At present, some of the construction projects such as the Shekou industrial area construction project at Shenzhen have already been started.

The 1978 National Final Accounting and 1979 National Budget of China

The 1978 national final accounting of China showed that in 1978 the annual financial income was 112.111 billion yuan, and annual financial expenditure 111.093 billion yuan, with a favorable balance of 1.018 billion yuan, thereby achieving the goal of striking a balance, with a small surplus. Compared to that of 1977, the financial income showed an increase of 28.2 percent, and the financial expenditures, 31.7 percent. Thanks to the efforts made in 1977 and 1978, the financial situation in China has changed from a state of stagnation and decline during the period when the "gang of four" was riding high, to a state of substantial increase in income; and from a state of difficulty and deterioration to a state of continual growth in fiscal resources, basically meeting the needs for the development of construction. This was a general reflection of the rapid recovery of our national finance and economy.

The substantial increase in financial income in 1978 was achieved as a result of the quick recovery and development of agricultural and industrial production, and the fact that relentless efforts were made to consolidate the enterprises and bring about profits instead of losses in their business operations. Of the total income, that from industrial and commercial taxes amounted to 45.1 billion yuan, an increase of 12.6 percent over that of 1977, and that from state-operated industrial enterprises 44.0 billion yuan, an increase of 35 percent. Deficits in industrial, communications, commercial, and agricultural enterprises were reduced by 2.6 billion yuan in 1977, and by another 3.25 billion yuan in 1978.

1978 Major Expenditures

Item	Expenditures (billion yuan)	Increase over that of 1977
Capital construction allocations	45.192	50.2%
Capital for development of potential and reform of enterprises, floating capital, geological prospecting expenditures, and industrial, communications, and commercial expenditures	16.778	22.6%
Expenditures for people's communes and agricultural expenditures	7.695	51.8%
Cultural, educational, public health, and scientific research expenditures	11.266	24.9%
National defense and war preparedness expenditures	16.784	12.6%
Administrative and management expenditures	4.908	13.3%

The increase in financial expenditures promoted the development of production, construction and other undertakings, and the improvement of the living conditions of the urban and rural people. Throughout the country, some 40 percent of the personnel and workers enjoyed increases in their wage grades, and an additional 20 percent enjoyed increases in pay to different degrees. In addition, a large number of personnel and workers had bonuses. By the end of 1978, as a result of wage readjustments, the personnel and workers in China enjoyed a total increase in pay of 2.75 billion yuan. The peasants enjoyed a total increase in income, from the distribution of income by their collectives, of 13.7 percent.

The 1979 national budget was adopted at the Second Session of the Fifth National People's Congress held on 1 July 1979. Total income and total expenditures were both 112.0 billion yuan, striking a perfect balance.

The total budgetary income for 1979 was at the same level as that in the national final accounting for 1978. This was because the 1979 income had already had deducted from it all the factors which would adversely affect it, such as the increase in the purchasing prices of agricultural and subsidiary products, the readjustment of the wages of some workers, and the reduction and exemption of some agricultural taxes. Also deducted was the capital needed to expand employment and implement the enterprise reserve fund system on a trial basis. All these factors amounted to a reduction in income of 16.6 billion yuan. If calculated on the basis of 1978 specifications, the annual income of 1979 should be 128.6 billion yuan, a 14.7 percent increase over 1978.

1979 Major Expenditures

Items	Expenditures (billion yuan)
Capital construction allocations	39.00
Expenditures for supporting people's communes and other agricultural undertakings	7.05
Capital for developing potential and reforming enterprises, and for trial production of new products	5.60
Additional allocations of floating capital for enterprises and bank credit funds	4.90
Cultural, educational, public health and scientific research expenditures	12.08
National defense and war preparedness expenditures	20.23
Foreign aid expenditures	1.00
National reserve funds	1.60

Financial income and expenditures for 1979 were arranged according to the policy, tasks and demands of readjusting the national economy, primarily:

1. Readjust the ratio between accumulation and consumption, and shorten the capital construction front. The proportion of allocations for capital construction in the budget was reduced from 40.7 percent in 1978 to 34.8 percent in 1979. At the same time, on the basis of developing production, the wages of some personnel and workers would be readjusted, the scope of employment expanded, the purchasing prices for agricultural and subsidiary products increased and the living standards of the people improved.

2. Readjust the proportionate relationships among agriculture, light industry and heavy industry, and strengthen the support for agriculture. In the field of capital construction investment, the ratio of investment in agriculture was increased from 10.7 percent in 1978 to 14 percent. This investment, plus the other items such as expenditures for supporting the rural people's communes, funds for agricultural undertakings, expenditures on rural areas disbursed from the floating funds of enterprises and from social relief funds, agricultural loans from banks, and the reduction in state income caused by the increases in the purchase prices of agricultural and subsidiary products and by the reduction and exemption of rural taxes, came to something over 24 billion yuan which was invested by the state in the development of agriculture in 1979. This high figure was unparalleled since the founding of the New China.

3. Concentrate industrial investments on the textile and light industries, the fuel and power industry, the building materials industry, and the communications and transportation industry. In 1979, the ratio of investment in the textile and light industries increased from 5.4 percent in 1978 to 5.8 percent. In addition, some capital and foreign exchange was allocated as loans for the adoption of new technical measures in support of the development of the textile and light industry. Furthermore, ample investments in the fuel and power industry and the communications and transportation industry were assured.

The Reform of the Financial System

For improving the readjustment of the national economy, a trial reform of the financial system was carried out in 1979. On 13 July 1979, the State Council promulgated five documents on the reform of the management system over state-operated industrial enterprises. In these documents, the following concerned the reform of the financial systems between the state and state-operated industrial enterprises:

1. Enterprises may now retain a certain percentage of their profits. This is a change from the practice of the enterprises getting their operational funds from the state on the basis of the total wages of their personnel and workers, and is a system directly associating the degree of success in operations and the development of production with the material well being of the personnel and workers. Under this system, the enterprises are permitted to retain a percentage of their profits based on their trades and their actual conditions. The enterprises may

use the profits retained by them as funds for the development of production, for the improvement of the collective welfare of their personnel and workers, and for issuing bonuses.

2. The depreciation rate of fixed assets has been gradually increased and the utilization of funds set aside for such depreciation has been liberalized. It is permitted to gradually increase the rate of depreciation to a rational proportion on the basis of profit increases. A larger portion of the funds set aside for depreciation is controlled by the enterprises themselves, and a smaller portion by the supervisory organizations concerned. Unused depreciation funds should be deposited in banks under a special account. The enterprises may use their bank deposits from depreciation funds and from their retained profits as collateral to get loans from banks to meet the needs for tapping potential and carrying out renovations or reform when necessary.

3. A system of compensation for the use of fixed assets has been adopted. Enterprises must pay a fixed-assets tax to the state according to the fixed assets in their use. These fixed assets may be sold or rented by the enterprises, but the proceeds obtained therefrom must be used for purchasing other necessary fixed assets.

4. A credit system for meeting all the needs for floating funds has been adopted. Enterprises get loans from banks to meet all their needs for floating funds. With regard to fixed funds, they should be authorized by the financial authorities in conjunction with the supervisory organizations concerned, and be obtained as loans from banks at low interest from allocations made by state finance. With regard to the above-quota funds needed by enterprises for seasonal use, they should be met with loans from banks at medium interest. Bank loans to enterprises for enabling them to overstock capital should be extended at high interest.

The various provinces, municipalities and autonomous regions and certain departments of the central government may select a small number of industrial and communications enterprises to put into practice the above measures on a trial basis, before applying them actively and steadily on a larger scale when sufficient experience is gained. In the case of the localities and departments which have already put into new systems of their own on a trial basis, they should all reorient their systems according to what is stipulated in the five documents issued by the State Council.

In 1979, the State Council also issued "Provisional Regulations Governing Capital Construction Loans," stipulating that capital construction funds should be met with loans from construction banks rather than from allocations from state finance. This will encourage the loan-receiving units to arrange their construction projects more carefully and carry them out more cost consciously to speed up their construction programs.

With regard to state farms, the state adopted the system of total financial responsibility to strengthen economic accounting, improve management, and give full play to economic organizations and measures.

In 1979, the state studied and made arrangements for the reform of the financial system between central and local authorities. In most areas in China, the system of "balancing expenditures against incomes, and sharing the total" was continued. To encourage the local authorities to overfulfill their tasks, it was stipulated that with regard to the overfulfilled portion, the percentage to be shared by the local authorities concerned would be raised to 50 percent if their regular share was 30 percent, and be raised by an additional 10 percent if their regular share was 50 percent or more. In Jiangsu Province, the system of "balancing expenditures against incomes and sharing the total at a fixed ratio to be maintained for 3 years" was continued on a trial basis. In minority autonomous areas, the existing financial system for minority autonomous areas is still in effect.

Commune Finance System in Trial Practice

The commune finance system is an integral part of the local financial system of the state. It embodies the distribution relationship of state finance within the framework of the people's commune, and takes part in the distribution and redistribution of the commune collective economy. The establishment of the commune finance system is a kind of reform for improving the rural basic-level financial management system.

According to the prevailing financial system, the communes in most localities are not charged with the responsibility of handling the financial income of the state nor of managing the various expenditures. They are responsible only for receiving and reporting their own administrative expenditures, exercising no financial power themselves. Following the rapid development of agricultural, forestry, animal husbandry, subsidiary and fishery production and that of the enterprises and business units of the people's communes, the state has increased its financial income and expenditures from year to year in dealing with the commune collective economy. At present, of county-level income and expenditures, 50 percent of the budgeted income and from 50 to 70 percent of the expenditures, including all administrative, cultural, educational and public health expenditures and an overwhelming portion of the capital expended in support of agriculture are transacted at the commune level. In localities where the commune finance system has been established, the local authorities must care not only for the budgetary income and expenditures of the state within the framework of communes, but also for the financial work of communes and commune-operated enterprises and undertakings. Generally speaking, these local authorities have adopted the system of "placing the commune finance under a unified leadership, combining vertical control with lateral control, and combined management of income and expenditures." In this way, the various expenditures which used to be allocated from county-level supervisory departments which exercised full control are now placed under the joint control of the county and commune authorities. The commune-level financial cadres and tax collectors who used to handle only the collection of taxes are now handling both the taxes and the profits, and both the income and expenditures. In this way a commune is able to make overall arrangements for all its budgeted income and expenditures and make the best use of all its funds, including the funds it has raised on its own, bank loans, and funds allocated by the state in support of agriculture.

The trial establishment of the commune finance system has gone through a course of developing from individual points to whole areas. The commune finance system was first established at Luohan Commune of Huangpi County of Hubei Province in 1970, then at Qingshiling Commune of Gai County of Liaoning Province in 1972, and then at Mazhao Commune of Zhouzhi County of Shaanxi Province in 1973. In December 1977, the Ministry of Finance convened at Huangpi County of Hubei Province a 10-Province Commune Financial Work Report Meeting to sum up and exchange experiences, and discuss and study the tasks, systems and structures of the commune finance arrangement. By 1979, the commune finance system was established on a trial basis in 19 provinces and autonomous regions, of which Hubei, Liaoning, Shaanxi, Hunan, Jiangxi and Jilin had the commune finance system established province-wide.

1979 Tax Revenue

China's tax revenue in 1979 was quite good. Although the state reduced to a further extent its rural taxes and reduced and exempted some other taxes in substantial amounts in 1979, the actual income from taxes still overfulfilled the state plan. With the exception of some individual taxes, the income from all taxes increased to varying degrees over that of 1978.

Tax revenue in 1979 accounted for one-half of the total budgeted state income. Of the total tax revenue, industrial and commercial taxes accounted for 78.5 percent, industrial and commercial income taxes 8.3 percent, customs duty 5.5 percent, agricultural (animal husbandry) taxes 5.4 percent, and from salt tax 1.8 percent. Various other industrial and commercial taxes, such as slaughter taxes, license taxes, real estate taxes, livestock trade taxes, and marketplace taxes amounted to an aggregate 0.5 percent.

Almost all the taxes in 1979 were paid via the socialist economy. Commercial, industrial, and other taxes paid by state-run enterprises accounted for 76 percent of all commercial, industrial, and other tax revenue, and of this, commercial and industrial taxes accounted for 84 percent of all commercial and industrial tax revenue. Commercial, industrial, and other taxes paid by the collective economy accounted for 23.4 percent of all commercial, industrial, and other tax revenue, and of this, the commercial and industrial taxes accounted for 15.7 percent of all commercial and industrial tax revenue.

Taxation System Reform

In the 30 years since the founding of the New China, the taxation system has undergone four major reforms. The first reform occurred in 1950 when the tax administration was unified under a new taxation system. At that time, there were fourteen taxes under the national unified taxation system. The state adopted a multiple taxation system where "many taxes were levied many times." As a result, industrial and commercial enterprises had to pay taxes at various production and marketing stages, and some of these taxes were levied repeatedly. The second reform was carried out in 1953, according to the principle of "simplying the taxation system while guaranteeing the tax revenues." Under this system, while the total amount of taxes remained basically the same, many taxes were combined and the tax levying measures were simplified. At the third reform carried out in 1958, the industrial and commercial taxes were further reformed. With little or no change in the tax burden as a whole, more taxes were combined, and the taxation rates and levying methods were simplified. In this reform, the industrial and commercial combined tax, the surtaxes, the urban realty taxes, the vehicle and vessel license taxes, and slaughter taxes were all combined into one single tax--the industrial and commercial tax. Under this system, state-operated enterprises were required to pay only one tax--the industrial and commercial tax (or salt tax)--and collective enterprises were required to pay only the industrial and commercial tax and the industrial and commercial income tax.

At the 1979 National Financial Conference and the National Taxation Conference, it was held that this overly simplified taxation system and the unified levying method were incompatible with production operations, cost control, economic responsibility and cost-effectiveness of the enterprises, nor with the complex economic conditions, making it difficult to bring the role of taxation as an economic lever into full play, and adversely affecting the development of foreign trade and the economic reform in China. For this reason, it was necessary to carry out a major reform of the taxation system. This reform was based on the principle of "developing the economy and assuring supplies," following objective economic laws, broadening the taxation avenue, and relying on taxation to regulate the incomes of enterprises. This would enable taxation to act as a lever in regulating the economy. In setting up a taxation system, it was necessary not only to study the existing taxes from an overall viewpoint, readjust them and make new laws accordingly, but also to revive some old taxes. In addition, some new taxes were adopted according to actual needs, so as to have taxes designed for different purposes which could complement one another while also playing their unique roles.

Tax reform is a task involving a wide field and is strongly policy oriented. It can only be carried out in order of relative importance and within our subjective capabilities, in coordination with the reform of the entire economic and financial system, by stages and in groups. The following is an important tax reform being carried out on a trial basis: On 13 July 1979, the State Council issued a decree to levy a fixed-assets tax on state-operated industrial and communications enterprises, requiring compensation from these enterprises for their fixed assets. This aimed at requiring the enterprises to shoulder necessary economic responsibilities and promote the usefulness of their fixed assets. This tax is levied on the basis of the original value of the fixed assets concerned, amounting to from 0.2 to 0.5 percent each month, according to different trades. In certain cases, this tax might be reduced, exempted, or doubled, as the situation calls for. Before the formal promulgation by the state of the fixed-assets tax law for state-operated enterprises, this tax is to be levied provisionally as a fixed-assets utilization tax among state-operated enterprises which have been granted greater autonomy on a trial basis. Wider application of this tax is to be carried out after sufficient experience is gained.

[Article by Wang Chengyao [3769 6134 1031]]

Tax Reductions and Exemptions to Promote the Development of the Collective Economy

In the past 2 years, the state has adopted a series of measures to reduce and exempt taxes to promote the development of the collective economy. One of the important measures was adopted in 1978 when the State Council approved and promulgated the "Report on the Question of Reducing Rural Taxes" by the Ministry of Finance.

Beginning in 1979, taxes on the rural collective economy were further reduced. The following were the main points:

1. With regard to industrial and commercial taxes, in the case of new commune or brigade enterprises which would have difficulty paying taxes during the early stages of their operations, the exemption of their industrial and commercial taxes would be extended from the 1 to 2 years as provided by the old regulations to from 2 to 3 years. This did not apply to such high-tax goods as tobacco, liquor, and cotton yarn. The minimum tax level was raised from the original 600 yuan to 3,000 yuan, with no tax levied on income under this and 20 percent tax on income above that limit. In minority areas where a four-tiered, progressive industrial and commercial tax was levied on a trial basis, the minimum tax level was also raised to 3,000 yuan. For enterprises operated by communes and production brigades and teams in frontier counties and minority national autonomous countries and banner, the period of tax exemption was extended to 5 years, beginning 1979. Old revolutionary bases (such as Northern Shaanxi) still suffering from economic difficulty and in which commune and brigade enterprises needed exemptions from industrial and commercial income taxes could report their cases to the State Council for approval.

2. With regard to agricultural taxes, for all production teams in low-yield areas where the average per capita grain ration was below the minimum level, agricultural taxes were to be exempted. With regard to the minimum agricultural income for taxation, each province, municipality and autonomous region should adopt its own standard on the basis of giving due consideration to the interests of the state, the collectives and the individuals, and according to the grain ration standards set by the state and other related rules and regulations, subject to the approval of the State Council. Reductions in or exemptions from taxes as required by minimum tax levels, after approval by the State Council, should be implemented level by level in those units needing such exemptions. No unit may be excluded. Otherwise, these localities would be taken as violating financial and economic discipline.

The implementation of the new rules and regulations governing the reduction and exemption of taxes will benefit the rural areas in China by a total of more than one billion yuan. This would be a great help to the work of promoting the development of enterprises operated by communes and production brigades and teams, consolidating the rural collective economy, speeding up the modernization of agriculture, promoting agricultural development and improving the living standards of the peasants.

In addition, the state also adopted some new regulations governing the reduction and exemption of taxes in the urban collective economy, taking into consideration the interests of the state, the collectives and the individuals. For instance, to help the employment of educated urban youths, all new collective enterprises will be exempted from income tax for a year from the first month of their productive operations. Enterprises still in difficulty after one year will be given further consideration. (In rural areas, all the farms and teams which were set up for the sole purpose of finding employment for the educated youths will be exempted from industrial and commercial taxes and industrial and commercial income taxes for the period from 1979 to 1985, whether or not they were newly established.) With regard to cooperative stores, surtaxes were abolished beginning in 1979. To advance the welfare of the personnel and workers of collective enterprises, it was stipulated that the handicraft, communications and transportation enterprises were allowed to set aside all their retirement funds for their personnel and workers before their income taxes were levied, instead of allowing them to set aside only a portion of their retirement funds before income taxes were levied. With regard to the retirement funds, funeral and burial funds, pensions for qualified personnel and subsidies for personnel and workers in difficulty, the cooperative stores were allowed, beginning in 1979, to set aside such funds from their income before their income taxes were levied, instead of taking them from their public welfare funds. Furthermore, the cooperative stores were allowed to set aside 7.5 percent of their total monthly wages to meet medical and welfare expenses for their members. All these measures resulted in income tax reductions. In addition, other tax reductions and exemptions were authorized to encourage collective economic units to make fuller use of their resources, treat their various wastes, and turn wastes into useful products.

The National Taxation Work Conference

The 1979 National Taxation Work Conference was held in Chengdu, Sichuan Province, in May 1979. Its mission was to carry out the spirit of the Third Plenum of the 11th CCP Central Committee through studying, given the shift in the party's work focus, what corresponding tactical shifts should be carried out in tax collection work in the new historical period, and how to comply with objective economic laws and give full play to the role of taxation in realizing socialism's modernization. The conference had a far-reaching and thorough discussion of the role of taxation as an economic lever in the new period. It was held that during the new period of national construction, taxation would play an important role as an economic lever in the economic life of the nation, helping to support the various economic policies, regulate production and consumption, and promote the planned and proportionate high-speed development of the national economy. It has an important role in encouraging enterprises to strengthen their economic accounting and improve economic results and management levels. It can help to carry out the principle of equality and mutual benefit in foreign trade and safeguard national sovereignty and economic interests. It can help to systematize the financial income of the state and supply funds for speeding up the realization of the four modernizations. It was realized that there were contradictions between the prevailing taxation system and the economic situation, and it was necessary in the course of readjusting, restructuring, consolidating and improving the national economy to carry out careful study and formulate overall plans to reform the taxation system, in order to establish a new taxation system meeting the demands of the new period. It was stressed at the conference that the taxation policy should strictly be carried out, stronger supervision should be exercised in the collection of taxes, all laws should be enforced and all law-breaking activities should be investigated to resolutely safeguard the financial income of the state and close all loopholes. We should also fulfill the general goal of "developing the economy and assuring supplies," promote production in every way possible, develop new financial resources and increase the financial income of the state.

Banking

The Four Changes and Eight Reforms in Banking

In February 1979, the People's Bank of China convened a conference in Beijing of the directors of all branches of the bank to study how to shift the focus of banking work to help bring about socialism's modernization of the state according to the guidelines of the Third Plenum of the 11th CCP Central Committee. It was stressed at the conference to observe objective economic laws and carry out the "four changes" in banking work as follows: (1) Change the practice of running things by purely administrative means to using economic methods to manage the economy and the banks, (2) change the practice of paying insufficient attention to capital management to paying more attention to the proper utilization of capital, on the basis of increasing capital resources, (3) change the practice of making loans simply according to production plans and commodity circulation plans to making loans according to the production and marketing contracts of enterprises in keeping with state plans, and (4) change the practice of requiring all banks in China to operate in the same style to requiring the banks at all levels to be managed as enterprises and strictly adopt the economic accounting system. The conference discussed and decided on the following important measures:

1. Appropriately raise the rate of interest in savings deposits, open more categories of savings accounts, and make great efforts to promote the increase of savings deposits in urban and rural areas to raise more funds for the four modernizations.

2. Bank loans are to be extended on a selective basis according to the degrees of success achieved by the enterprises in fulfilling state plans, carrying out economic contracts, conducting their operations, and maintaining their credit.

3. Restore and establish specialized banks and companies. Restore the Agricultural Bank of China as a bank directly subordinate to the State Council under the control of the People's Bank of China, to strengthen agricultural credit work and support the development of agriculture. To strengthen foreign exchange work, it is suggested to reassign the Bank of China as an organ directly subordinate to the State Council under the control of the People's Bank of China. To strengthen printing work, it was decided to set up a general printing company. Branches of the insurance company are gradually being established at all localities of the People's Bank of China in the various provinces, municipalities and autonomous regions and at important ports, according to the expanding needs of banking operations. Domestic insurance is being restored step by step.

4. To assist in solving problems overlooked by state plans, the banks may, with certain limitations and under certain conditions, extend short term and intermediate term loans to enterprises under the ownership of the whole people to engage in the construction of small hydroelectric and thermal power plants or to purchase equipment to enable them to do a good job in developing their potential and carrying out renovations and reforms.

5. Change the practice of extending and recalling all loans only by the main office of the People's Bank of China, and grant greater authority and responsibility to subordinate banks in raising and using credit funds. In the planned control of

loans, the system of "overall planning, level-to-level control, associating deposits with loans, and controlling balances" is being adopted on a trial basis, i.e., for the main office of the People's Bank of China to set the amount of balance between credit income and expenditure to be kept by its branches in the various provinces, municipalities and autonomous regions according to the credit plan authorized by the state. Under conditions where their banking deposit plans are fulfilled and the aforementioned balance is kept within the set limit, the various branches of the People's Bank of China may extend more credit if they have more deposits or if they can speed up the turnover of credit funds.

6. The banks should carry out their operations as enterprises and carry out strict economic accounting. All banks subordinate to the provincial, municipal and autonomous regional branches of the People's Bank of China and all specialized banks and companies should apply for the authorization of their funds according to established standards and rules and regulations, and manage their operations and treat themselves as enterprises. Fund transactions between banks must not be done without computing due interest.

7. Restore and establish banking research institutes to strengthen banking research work. The various provincial, municipal and autonomous regional branches of the People's Bank of China should pay due attention to the establishment of banking research institutes manned by the necessary research personnel.

8. Change the banking cadre management system and intensify the training of cadres. Change the banking cadre management system to the system of placing cadre management under the dual leadership of the bank and local authorities, with greater emphasis on the bank leadership. A major effort should be made to do a good job in operating banking institutions and secondary vocational banking schools, and strengthen the education and training of cadres at their posts, so that a great number of knowledgeable economics and banking experts can quickly be trained in a planned manner.

With the approval of the State Council, the above reform measures were put into practice, or practiced on a trial basis in 1979.

Reinstating Agricultural Bank of China

The CCP Central Committee and the State Council decided to reinstate the China Agricultural Bank to strengthen management of agricultural funds to develop rural banking service, to develop agricultural production rapidly and to realize the four modernizations.

On 23 February 1979, the State Council issued the "Notice on Reinstatement of the China Agricultural Bank." In this notice, it was stated that the main tasks of the China Agricultural Bank are to assume overall control of the funds for agriculture, handle rural credit, assume leadership over rural credit cooperatives, and develop rural banking services. The following are the businesses it handles:
(1) Study, allocate, distribute and supervise the use of the funds assigned by the Ministry of Finance for agriculture, the deposits made by commercial departments for purchases, the agricultural loans extended by banks and credit cooperatives, and the funds for agriculture raised by operational departments themselves.

(2) Agricultural banks and credit cooperatives handle the deposits and loans for rural people's communes, production brigades and teams, enterprises operated by communes and production brigades and teams, state-operated agricultural enterprises, agricultural-industrial-commercial combined enterprises, and supply and marketing cooperatives. (3) Credit cooperatives are collective banking units as well as the basic-level units of agricultural banks. The credit cooperatives handle the deposits and loans for the basic accounting units of the rural people's communes, the enterprises operated by communes and production brigades and teams, and individual commune members. Agricultural banks handle the deposits, loans, urban-rural accounting and cash management for state organizations, associations, schools, enterprises and business units in rural areas. (4) Give assistance to basic accounting units of rural people's communes in their accounting work, and to communes and production brigades and teams in handling their funds in a way to their best advantage.

The Agricultural Bank of China has branches at different levels. The main office at the ministry level is directly subordinate to the State Council, and is under the control of the People's Bank of China. It has provincial, municipal and autonomous regional branches, prefectural main sub-branches, county sub-branches, and business offices in administrative units below the county level. The agricultural banks assume overall leadership over the credit cooperatives established in rural people's communes and the credit service offices established in production brigades. The Agricultural Bank of China has more than 27,000 branches and sub-branches throughout the country, employing more than 230,000 personnel and workers. There are more than 59,000 credit cooperatives employing more than 260,000 full-time cadres, and more than 350,000 credit service offices employing more than 360,000 part-time personnel. These units form a comprehensive rural banking network.

In September 1979, the Agricultural Bank of China convened its first national conference of branch directors since its reinstatement to discuss the following issues: Agricultural credit funds should be increased progressively to help in the development of agricultural modernization; Agricultural credit funds should be used mainly to assist communes and production brigades to develop commodity production, diversified economy and enterprises, to continually improve their financial positions; Agricultural credit funds should be placed under tighter management; the credit fund management system of communes and production brigades should be reformed; and efforts should be made to bring into full play the role of agricultural loans to promote and supervise the development of agricultural production. At the conference, it was requested that the agricultural banks at all levels should, in disbursing agricultural loans, adhere to the principles of "taking food grain as the key link, achieving over 11 development, taking local factors into consideration, and concentrating the use of funds appropriately," and "simultaneously developing agricultural, forestry, animal husbandry, subsidiary and fishery production," and give great support to communes and production brigades to quickly develop commodity production. Poor communes and production brigades should be assisted in adopting means to increase their production and income, to open more avenues for increasing financial resources, and to improve their status through the development of production. But credit cannot be used as relief funds. Efforts should be made to overcome the erroneous view that abundance reflects capitalism and poverty socialism, and that it is wrong to extend loans to rich production brigades and correct to extend loans to poor production brigades. In summing up the historical experiences in the management and utilization of agricultural credit in the 30 years since the founding of the nation, the conference stressed the importance of upholding the fundamental principle of "recalling loans upon maturity" in agricultural credit management on the part of agricultural banks. In particular, cases where the borrowers encountered difficulty in repaying their loans, the repayment date may be postponed, but the repayment itself must not be exempted, because it is in violation of socialist economic principles and the established credit rules and regulations.

Reform of the Credit Management for Rural Communes and Production Brigades

In the past, the banks' management methods for credit funds to communes and production brigades were basically controlled by the main office of the banks. Under that practice, the village deposits received by all local banks were handed over to the main office, and the agricultural credit from the main office was issued through banks at the different levels in a controlled manner according to set standards. Although this practice enabled the bank to maintain good balance in agricultural credit, it was not conducive to the development of enthusiasm on the part of the central and local authorities concerned.

To fully develop local enthusiasm to raise funds and manage them properly at each level, combining authority and responsibility and coordinating deposits, loans, and collections to better support the overall promotion of agricultural production and progressively realize agricultural modernization, the Agricultural Bank of China decided that beginning 1980 a credit management system in the communes and brigades of "linking deposits to loans to assume a balance" be implemented under a state unified system of planning and policy. This management system calls for the main office of the Agricultural Bank of China to set a balance between total deposits and total loans allowed for each provincial, municipal and autonomous regional branch corresponding to its year-end balance. Those with deposits exceeding loans would be required to forward a set amount of funds to the main office, and those with loans exceeding deposits would be supplied with a set amount of funds to meet their needs for the loans extended. After these standards are set, the various branches will be allowed to make use of the surplus funds they obtain from absorbing more deposits or recalling more loans than needed for meeting the set standards. The main office of the Agricultural Bank of China will allow each branch to keep a given amount of cash to be used as a contingency fund. This new credit management system for communes and production brigades has been put into trial practice among the provincial, municipal and autonomous regional branches of the bank beginning 1980.

Banks Extend Credit Selectively To Reward Excellence

The People's Bank of China extends loans to industrial and commercial enterprises selectively, assisting those with superior performance. For a bank to regulate the economy with economic methods in carrying out its credit work, this is a necessary measure. It marks a change from the practice in the past where credit was granted without questioning the quality of operations and the marketing conditions of the enterprises concerned. This measure will enable credit to act as an economic lever to change the situation where the enterprises cared little about the economic yields of their operations, to the advantage of the readjustment and development of the national economy.

This practice of discriminatory assistance is done in the following manner: 1) Discrimination in trades. In the readjustment of the national economy, more favorable loan considerations should be given to the light and textile industries and the energy industry. Some restrictions should be imposed in granting loans to the machine-building and other industries. This will curtail the production of products in abundant supply to promote the production of products in short supply and so divert financial and material resources of the state to the production of products more urgently needed by the state and the people; 2) Discrimination in enterprises according to the quality of operations. Banks at the various localities will classify enterprises through careful study on the basis of local conditions into three categories, good, average and poor, according to the following criteria: their fulfillment of state plans, their fulfillment of contracts, their operational situation and their credit. Favorable considerations will be given to the enterprises of the first category, so that loans are extended to them on a priority basis. Enterprises of the second category should be assisted in developing their potential to qualify for loans in appropriate amounts. With regard to the enterprises of the third category, more restrictions should be imposed on their loans to promote their readjustment and improvement; and, 3) Discrimination in enterprises according to their products. Favorable consideration should be given to enterprises whose products are of good quality and in demand on the market. Restrictions should be imposed on enterprises whose products are of poor quality and unpopular on the market.

Based on these principles of selective assistance, in 1979, the People's Bank of China started to grant medium- and short-term loans for the procurement of equipment to enable the enterprises to develop their potential and carry out renovation and reform. This type of loan aims mainly at giving support to the textile and light industrial enterprises and enterprises engaged in the production of products in short supply, particularly those whose products are of good quality and whose supply of raw materials and energy are assured, and those noted for quick and abundant returns on their investments and their quick accumulation of funds and foreign exchange. Although this type of loan is not substantial and has been started relatively recently, it has yielded marked results in assisting enterprises in carrying out technical renovations and developing their potential, and has therefore won the appreciation and welcome of the enterprises and the departments concerned.

State Funds Give Way to Bank Loans for Capital Construction Investments

In August 1979, the State Council approved the "Report on the Trial Method of Using Loans to Carry Out Capital Construction" and the "Trial Regulations Governing Loans for Capital Construction" submitted by the State Planning Commission, the State Capital Construction Commission and the Ministry of Finance, and decided to use loans for capital construction on a trial basis.

It was a major reform in the capital construction management system to shift from the allocation of funds by the state to the extension of loans by banks for capital construction. It had long been standard practice for the state to allocate non-compensatory funds to the construction units for capital construction. Following the shift from state funds to bank loans, the capital construction investments were made in the form of repayable loans. This was more in keeping with the principle of regulating the economy according to economic laws. Under the guidance of state plans, greater roles were played by economic organizations and economic means.

Capital construction loans must be repaid by the borrowers themselves. A borrower must be an industrial, communications, transportation, farm, animal husbandry, aquatic production, commercial, or tourist unit with independent accounts and capable of meeting the repayments. With regard to the administrative units, non-profit units and projects required by state plans, their expenditures are still to be met with state allocations.

To qualify for loans, a unit engaged in capital construction must have approved plans and preliminary designs which are included in intermediate- and long-term construction plans and in the annual construction plan. A unit engaged in production must be screened by a bank to see if the products are in popular demand on the market, the workers have mastered the technology concerned, and the conditions for production and construction have been met satisfactorily.

To assure the continuation of capital construction loans on a trial basis, and to encourage borrowing units to go into production on or ahead of schedule, the loan regulations stipulate that, for projects with loan contracts already signed and which have begun construction, the planning and management departments must arrange the capital construction plans in subsequent years in keeping with the loan contracts and in keeping with the degree of progress of the construction, thereby ensuring its continuation. Supply authorities must assure the supply of equipment, materials and goods. After an enterprise is completed and goes into production, during the period of loan repayment, the enterprise may keep all fixed assets depreciation funds and profits to repay the loan. Enterprises which have been completed ahead of schedule and which have their loans repaid ahead of schedule, may retain all the funds earmarked for repaying loans to develop production or improve the welfare of the personnel and workers during the period originally set for loan repayment. In the case of enterprises which are unable to make the loan repayment according to schedule, the loans should be repaid from their funds set aside for renovation and reconstruction. They cannot meet loan payments at the expense of production or profits.

Upon receipt of the notice from the State Council, Shanghai, Jilin, Henan and Jiangsu started to implement this system on a trial basis among some construction units in 1979. By March 1980, some 150 projects were shifted from state allocations to bank loans. These projects were distributed in Shanghai, Jilin, Henan, Hubei, Fujian, Zhejiang, Ningxia, Hebei and Liaoning. Some of them were under the direct jurisdiction of the Ministry of Water Conservancy and Power and the Ministry of Textile Industry.

The experiences gained in these projects showed that the practice of shifting from state allocations to bank loans has readjusted the economic relationship between the state and the enterprises in the utilization of investments, established an organic relationship between economic responsibility, economic power and economic benefits, brought into full play the work enthusiasm of the enterprises and their personnel and workers, encouraged borrowers to make detailed calculations of the economic yield, select the construction projects, carry out the construction most economically, and speed up the progress of construction to bring in their economic yields as early as possible.

State Foreign Exchange Control Bureau Established

The State Foreign Exchange Control Bureau (abbreviated FEB) was established on 13 March 1979. This bureau and its branches are organs of the People's Republic of China in charge of the control of foreign exchange.

The following are the duties of the FEB: To formulate detailed rules and regulations governing the control of foreign exchange, publish the rates of exchange between the RMB and foreign currencies, assume overall control of foreign exchange funds, formulate the overall plan for foreign exchange incomes and expenditures and keep them largely in balance, and examine and supervise foreign exchange incomes and expenditures whether or not they are incurred in foreign trade.

The FEB is directly subordinate to the State Council, under the control of the People's Bank of China. Its main office is in Beijing, with branches in a majority of the provinces, municipalities and autonomous regions. These branches are under the leadership of the main office in their business operations. In localities where no branches of the FEB are available, the People's Bank of China is authorized to handle foreign exchange affairs.

The Bank of China Expands Its Operations

The Bank of China specializes in foreign exchange and the handling of all kinds of foreign exchange businesses for the People's Republic of China.

Following the continuous development of China's foreign trade and international activities, the Bank of China has rapidly expanded its operations and increased its international accounting tasks. To meet the requirements of the new period and to shift the focus of work to socialist construction, the State Council on 13 March 1979 made the Bank of China an organ directly subordinate to the State Council, under the control of the People's Bank of China, and authorized the Bank and its branches, sub-branches, and local offices to increase their personnel.

The following are the tasks within the scope of operations of the Bank of China: To manage the foreign exchange buying and selling of all currencies; to manage the international accounting of foreign exchange, whether or not it involves foreign trade; to make foreign exchange loans in foreign trade in a planned manner; to handle deposits in foreign currencies and foreign deposits in people's currency, to handle remittances from overseas Chinese in foreign countries to China according to state policy governing such remittances; to handle international remittances, issue and cash foreign exchange certificates and traveler's checks, conduct credit investigation and information tasks; and to handle other tasks included in the operations of an international bank.

The Bank of China in the various localities may be entrusted by Chinese citizens to carry out non-trade transactions abroad, such as the sale, exchange and purchase of foreign stocks. It may receive dividends, transferring back to China foreign deposits and interests, sell their properties in foreign countries, and handle the inheriting of properties in foreign countries.

The main office of the Bank of China is in Beijing. It has 81 branches, sub-branches and offices in port cities and frontier areas, including 34 branches, 35 sub-branches and 12 offices. More will be established in the future. There is one branch in Hong Kong. In foreign countries, it now has a London branch and a Luxemburg branch in Europe, and a Singapore branch and a Tokyo office in Asia. It will establish more branches and offices in major world banking centers in the future. The Bank of China has established business relations with the banks of many foreign countries. By the end of 1979, it had business relations with 2,534 branches of 948 banks of 142 countries and regions in the world.

Overseas Chinese Remittances and Related State Policy

The work of handling remittances from Overseas Chinese constitutes an important part of the policy "making it easy to make remittances from foreign countries to advance the interests of Overseas Chinese." These remittances are one of the main sources of non-trade foreign exchange, playing a positive role in developing production in the native counties of the Overseas Chinese, improving the livelihood of their dependents, bringing about the four modernizations in these counties, and providing foreign exchange funds for the state.

In the past, because of the serious intervention and sabotage of Lin Biao and the "gang of four" against the state policy concerning Overseas Chinese, remittances from the Overseas Chinese were undermined. Lin Biao and the "gang of four" widely spread the fallacies such as "remittances from Overseas Chinese are useless," "remittances from Overseas Chinese are dangerous," "remittances from Overseas Chinese are as corrosive as sulphuric acid," and "socialism can be built without any remittance from Overseas Chinese." They viciously attacked the families receiving remittances from relatives overseas, and even went so far as to withhold and confiscate such remittances. This interrupted the association between Overseas Chinese and their dependents in China. In some cases, the interruption still prevails today.

After the "gang of four" was smashed, the State Council reiterated its policy to safeguard remittances from Overseas Chinese, acknowledging the right of the recipients to hold and use such remittances. Today, the volume of these remittances has rapidly increased. To improve the livelihood of the dependents of the Overseas Chinese, beginning April 1978 the state restored the supply of materials to be purchased with remittances from Overseas Chinese. Many stores were established in the various localities to sell grain, edible oil, non-staple food items and daily necessity manufactured goods to foreign remittance holders on the basis of the foreign remittance coupons they had. The overseas Chinese dependents were allowed to buy 30 yuan's worth of commodities (10 yuan worth of grain, edible oil and non-staple food items and 20 yuan worth of industrial products) upon surrendering a 100-yuan foreign remittance coupon. In addition, the overseas Chinese were encouraged to send money to their dependents to build living quarters, allowing them to buy construction materials or buy houses with the remittances.

RMB Traveler's Checks and Foreign Exchange Cashier's Offices

Traveler's checks--To meet the needs of Overseas Chinese and compatriots from Hong Kong and Macao who returned to China to see their relatives and friends and the needs for the development of tourism in China, beginning 20 January 1978 the Bank of China started to sell RMB traveler's checks in the denominations of 50 and 100 yuan. These checks are honored within the first 6 months of issuance. In case of their being lost or stolen, the buyers may apply for reimbursement according to established rules and regulations. Unused and expired travelers' checks may be cashed in at the issuing banks.

The RMB traveler's checks are obtainable at the Bank of China in Hong Kong and Singapore and at the following banks in Hong Kong and Macao: Jiaotong, Xinhua, Jincheng, Zhejiang Xingye, Guohua, Guangdong, Zhongnan, Yanye, Nanyang Shangye, Baosheng, Huaqiao Shangye, Jiyou, Nantong and their branches. In China, the traveler's checks are obtainable at the business department of the main office of the Bank of China and its branches in Beijing, Shanghai, Tianjin, and Guangzhou.

RMB traveler's checks may be cashed only in China. They may be cashed at the Bank of China, its various branches, and its authorized agents. By March 1980, more than 1,080 branches, sub-branches and authorized agents of the Bank of China were in operation throughout the country to cash RMB traveler's checks. To the delight of foreign visitors, Overseas Chinese, and the compatriots from Hong Kong and Macao, large numbers of stores, hotels, restaurants, airports, train stations, bus stations, and sea and river ports now accept RMB traveler's checks.

Foreign Exchange Cashier's Offices--There are three classes of foreign exchange cashier's offices to cash foreign currencies, foreign currency notes, RMB traveler's checks. Class 1 may cash foreign currencies, foreign currency notes and RMB traveler's checks; class 2 may cash foreign currencies and RMB traveler's checks; and class 3 RMB traveler's checks only.

RMB Foreign Exchange Rates

The foreign exchange rates of the RMB are set by the State Foreign Exchange Control Bureau, published by the Bank of China and reported daily by the XINHUA News Agency in Chinese, English and French.

The foreign exchange rates of the RMB are set according to the principles of independence, equality and mutual benefit, beneficial to the development of the national economy and foreign trade and to the work of upholding the value of the RMB.

With regard to the foreign exchange rates of the RMB, there are the buying prices and selling prices. The buying prices are the prices paid by the bank in buying the foreign currencies, and the selling prices are the prices of the foreign currencies being sold by the bank. The median prices are the prices derived by adding the buying and selling prices concerned and dividing the resultant figure by two.

Since 1973, when the capitalist nations adopted floating exchange rates, the exchange rates of their currencies have fluctuated frequently according to the market supply and demand of their currencies. To avoid the adverse effect of the economic depression of capitalist nations, maintain the stability of RMB, and keep the exchange rates of the RMB on a rational level, it was decided to readjust periodically the exchange rates of the RMB. In 1979, there were published exchange rates between the RMB and 26 foreign currencies. During that year, the exchange rates of the RMB against these foreign currencies have generally risen to different degrees, as shown in the following table:

1 人民币外汇牌价

2 国家外汇管理总局　　3 单位：人民币元

Sino-U.S. Agreement on Settlement of Asset Claims

In 1950, following the outbreak of the war of aggression against Korea by the United States, the United States imposed embargo against China and, on 17 December 1950, froze all the assets in the United States belonging to Chinese government organizations, banks, enterprises, business units, associations and individuals. On 28 December 1950, China adopted the same measures against U.S. properties in China and froze U.S. banking deposits in China.

In the course of normalizing relations between the two countries, both sides started to submit demands since 1972 on its assets held by the other side. To develop bilateral economic and trade relations on the basis of equality and mutual benefit and in the spirit of the Joint Communique on the Establishment of Diplomatic Relations Between China and the United States, the two sides conducted negotiations on this matter. On 11 May 1979, the Chinese and U.S. governments signed an agreement on the settlement of asset claims. The agreement stipulated that the Chinese Government would pay by installments a total of US$80.5 million to the U.S. Government to meet its asset claims as a total and final settlement, and the United States would unfreeze our assets, so that the Chinese asset owners could reclaim their assets individually from the holders in the United States. In carrying out this agreement, for the protection of the legitimate rights and interests of Chinese units and individuals, the State Council on 9 September 1979 issued a decree authorizing the Bank of China to act on behalf of the Chinese state organizations, state-operated enterprises and business units, associations, schools, former privately operated and jointly operated industrial and commercial enterprises which had been converted to state operation, and Chinese citizens to reclaim and repossess assets frozen in the United States. The decree also stipulated that no unit or individual was allowed to repossess, sell, or transfer their frozen assets in the United States without the consent of the Bank of China. On the same day, the Bank of China issued a notice calling on all owners of assets in the United States to register their claims for the reclamation and repossession of such assets. The reclaimed and repossessed assets were handled according to established rules and regulations concerned.

Sharp Increase in Savings Deposits

In the 30 years since the founding of New China, the funds accumulated in the form of savings deposits have served as a reliable, stable and ever-increasing supply of funds for production and construction for the state. In this 30 years, the amount of savings deposits has increased steadily at a rate much faster than the rate of increase in funds lent out as credit. During the period of the First Five-Year Plan, funds to be lent out as credit increased at an average rate of 14.9 percent, but the amount of savings deposits increased at 26.5 percent per annum. During the three years of economic readjustment, while the funds to be used as credit showed no increase, the amount of savings deposits increased at a rate of 18.5 percent per annum. After the "gang of four" was smashed, the funds for credit increased at a rate of 9.6 percent, and the amount of savings deposits at 18.4 percent per annum. Following the development of production and the increase in income of the masses, the amount of savings deposits as a proportion of the amount of wages also increased. This ratio was 3.26 percent during the period of the First

Five-Year Plan, 3.1 percent during the three years of economic adjustment, 4.0 percent during the period 1977 to 1978, and 8.2 percent in 1979. The continual increase in savings deposits will provide more and more funds for the development of the national economy.

In 1979, the savings deposits in urban and rural areas in China increased at a rate unparalleled in history. Urban savings increased by 4.7 billion yuan, rural commune members savings by 2.2 billion yuan. By the end of 1979, the amount of urban savings deposits in China totaled 20.26 billion yuan, showing an increase of 30.8 percent over that of 1978. Of this total, 18 percent was in checking accounts, and 82 percent in time-deposit accounts. Thirty percent of the time deposits belonged to the long-term category, ranging from 3 to 5 years. The amount of savings deposits made by rural commune members in 1979 totaled 7.84 billion yuan, showing an increase of 40.8 percent over that of 1978.

In 1979, the amount of urban savings deposits in minority areas showed even faster increase than other areas. Savings in Ningxia increased by 35 percent, in Guangxi by 32.29 percent, and in Nei Monggol by 30.77 percent, surpassing the average increase in urban savings in China as a whole.

In 1979, the number of urban savings banks in China increased by more than 600, to a total of more than 6,000, and the number of their personnel increased by more than 6,000, to a total of more than 50,000. Savings units have also been established under the sponsorship of the ranks in government organizations, enterprises, and mass organizations in cities all over China to handle savings deposits by their personnel.

[Article by Liu Yansun [0491 3601 5549]]

Increased Interest on Time Deposits

On 1 April 1979, the State Council authorized increases in the interests on time deposits. In China, interest is calculated monthly. The interest on one-year, fixed-term, lump-sum deposit and withdrawal savings accounts was increased from 2.7 percent to 3.3 percent per annum. That on lump-sum deposit and withdrawal half-year fixed-term savings was increased to 3.0 percent per annum, on 3-year deposits to 3.75 percent per annum, and on 5-year deposits to 4.2 percent per annum. With regard to savings deposits made by the Overseas Chinese, the interest on one-year lump-sum deposit and withdrawal accounts was increased from 3.3 percent to 3.9 percent per annum, and on 3-year fixed-term savings to 4.2 percent, and that on 5-year deposits 4.5 percent. During the initial period after the founding of New China, because of the inflation inherited from the old China, interest rates had been high. At that time, the monthly interest rate on one-year fixed-term savings deposits was 21 percent. Following the recovery and development of the national economy, the gradual elimination of inflation and the gradual stabilization of commodity prices, major adjustments in interest rates were made on several occasions. In 1971, because of the interference and sabotage of Lin Biao and the "gang of four," the interest rates on savings deposits were lowered to an unreasonable level, making it necessary to raise the rates to a suitable extent in 1979. In April 1980, interest rates on savings deposits were readjusted upward once again in line with actual conditions to bring the role of interest rates as an economic lever into full play.

The Development of Chinese People's Insurance

The People's Insurance Company of China was established in October 1949. It is the only state-operated insurance company in China, under the leadership of the People's Bank of China. It has 76 branches and sub-branches in major ports and cities of the various provinces, municipalities and autonomous regions.

The People's Insurance Company of China handles mainly the following overseas insurance businesses: insurance on import-export freight shipping which is related to foreign trade and to economic exchange with foreign countries, and insurance for ocean-going ships, for planes flying international routes, for persons and properties of foreign organizations in China, and for construction projects, as well as international reinsurance. Following the adoption of diversified trading methods by China in its foreign trade, the insurance company also began issuing insurance on the processing of materials supplied by customers, insurance on compensatory trade, warranty insurance, and other new forms of business. In addition, the insurance company has designated more than 300 inspection and claims settlement agents to examine goods and ships in more than 100 countries and regions. On 8 July 1979, the Standing Committee of the National People's Congress promulgated the "Law Governing the Operations of Joint Ventures" stipulating that joint ventures must buy insurance from a Chinese insurance company. This helped in the expansion of business of the People's Insurance Company of China. It has now established direct or indirect insurance business division arrangements with more than 900 insurance and reinsurance companies in 115 countries and regions, joined the Asian-African Insurance and Reinsurance Association and its reinsurance bloc, and become a member of the Asian Reinsurance Corporation.

Gradual Recovery of Domestic Insurance Business

In April 1979, the State Council authorized the People's Bank of China to gradually resume domestic insurance business.

At the time of its establishment in 1949, the People's Insurance Company of China offered domestic insurance for properties, transportation of goods and materials, means of transportation, persons, livestock, and crops. This type of business was discontinued during the period 1958 to 1978. The advantage of insurance was shown in the following, based on the experience of the insurance company in the first 10 years after the founding of New China: First, by paying a small premium, an enterprise or individual could quickly obtain economic compensation in the event of unexpected loss, making it possible for them to recover and develop production, strengthen their economic accounting system, and improve the welfare of the masses. Second, the insurance company could contribute to the prevention of disasters and losses in cooperation with the authorities concerned, thus reducing the incidence of disasters and mishaps and increasing the safety of social wealth. Third, after expenditures for loss compensation and business operations, the premiums received by the insurance company each year were kept as insurance reserve funds of the state, which could be used as bank credit funds in support of socialist construction. In view of these advantages, a national insurance work conference was held in November 1979 to make arrangements for resuming domestic insurance business gradually and steadily in 1980 to advance the interests of the masses and production.

China Joins the Asian Reinsurance Corporation

The Asian Reinsurance Corporation is an intergovernmental organization. It is one of the regional cooperation projects undertaken by the U.N. Asian and Pacific Economic and Social Council, the purpose of which is to require that, to the extent possible, the reinsurance business among the developing countries in the Asian and Pacific region be exchanged among the nations of the region, so as to accumulate foreign exchange for insurance in this region. The committee estimated that during 1974, as much as US$200 million in foreign exchange flowed into the developed countries in the form of reinsurance premiums from just 10 major developing countries in the Asian and Pacific Region. The establishment of the Asian Reinsurance Corporation would curtail the outflow of such premiums from the Asian and Pacific region and raise the technical standards of insurance in that region.

In October 1974, under the sponsorship of the U.N. Trade and Development Conference and the U.N. Asian and Pacific Economic and Social Council, a round-table conference was held by the insurance supervisors and representatives of the insurance circles of the Philippines, Thailand and 16 other states and regions to propose the establishment of an Asian reinsurance corporation. This was followed by a preparatory conference held in January 1976, at which an agreement to establish the Asian Reinsurance Corporation was reached. By 1978, this agreement had been signed by the governments and authorities of Afghanistan, Bangladesh, India, Iran, the Philippines, Sri Lanka and Thailand.

To lend support to the cooperation of the developing countries in Asia and the Pacific Region in the reinsurance business, on 29 March 1979 the State Council of China ratified the "Agreement to Establish the Asian Reinsurance Corporation." That marked the first occasion of China's participation in a U.N. organization for trade cooperation.

An inaugural meeting was held by the Asian Reinsurance Corporation in Bangkok, Thailand on 28-31 May 1979. China assigned Lin Zhenfeng, Deputy General Manager of the People's Insurance Company of China, to attend on its behalf. The agreement to establish the Asian Reinsurance Corporation provides that all developing countries in Asia and the Pacific Region may apply for membership. Each member nation must contribute to the membership fund in the amount of US$500,000.

By decision of the first board of directors meeting, the Asian Reinsurance Corporation was set up in Bangkok, Thailand. The corporation started its business operations on 1 January 1980.

The Issuance of Commemorative Gold Coins in Celebration of the 30th Anniversary of the Founding of the People's Republic of China

In celebration of the 30th anniversary of the founding of the People's Republic of China, the State Council authorized the People's Bank of China to issue a set of commemorative gold coins. This is the first time since the founding of the New China that precious commemorative gold coins have been issued for sale abroad. These coins were produced by the China Mint, a subordinate unit of the People's

Bank of China, and marketed by the Bank of China. On 13 September 1979, these coins went on sale simultaneously in China and in Hong Kong to buyers throughout the world. There are a total of 70,000 sets, and each set is composed of four gold coins. All four coins bear the national symbol of the People's Republic of China on their obverse side. Their reverse sides bear the pictures of Tian'anmen Square, the Great Hall of the People, the Monument of the People's Heroes, and the Chairman Mao Memorial Hall, respectively. Each coin, 22K in gold content, is 27 millimeters in diameter, containing 0.5 ounce of pure gold, with a face value of 400 yuan in renminbi [people's currency]. Because of their delicate designs and beautiful appearances, these commemorative coins have received an enthusiastic welcome from coin collectors at home and abroad.

Foreign Trade

[Article by Li Kanghua [2621 1660 5478] and Wang Shouchun [3769 1108 2797]]

The Growth of Foreign Trade in 1979

In 1979, China's foreign trade showed much growth, and its foreign trade volume reached a new record, amounting to 45.46 billion yuan, showing an increase of 28.1 percent over the 35.5 billion yuan of 1978. In particular, the volume of exports totaled 21.17 billion yuan, showing an increase of 26.3 percent over the 16.76 billion yuan of 1978; and the volume of imports totaled 24.29 billion yuan, an increase of 29.6 percent over the 18.74 billion yuan of 1978.

In 1979, China's foreign trade was conducted according to the principles of "attaching first importance to exports, coordinating imports with exports, using exports as a yardstick to set the scope of imports, and striking a balance between imports and exports." As a result of great efforts to increase the supply of products to continually increase exports, the export of agricultural and subsidiary products increased by 5.7 percent, that of the textile and light industrial products by 21.2 percent and that of heavy industrial products by 58.0 percent. Industrial and mining products increased as a percentage of exports by a large margin as compared to 1978. Major export commodities included crude oil, cotton cloth, silk piece goods, clothing, raw silk, cotton textile products, rice, live hogs, frozen prawns, tea, feathers, knitwear, and tungsten ore. To improve the quality, design and variety of the export commodities to standards meeting the demands of the world market and to increase their production, by the end of 1979 China established 16 export commodity production complexes, more than 100 individual export commodity production bases for live hogs, beef cattle, apples and goat hides, and 94 factories, mines and workshops specializing in producing export commodities. To meet the needs of the four modernizations, more advanced technology and equipment were imported in 1979, showing an increase of 190 percent over that of 1978. Compared to that of 1978, the import in 1979 of agriculture-oriented supplies showed an increase of 20.7 percent, textile and light industrial raw materials 15.6 percent, and consumer goods 30 percent. Imports of steel products, nonferrous metals, pig iron, and iron ore was lower in 1979 than in 1978. Besides advanced technology and equipment, the following were the major commodities imported in 1979: steel products, motor vehicles, ships, mining machinery, machine tools, chemical fertilizer, agricultural chemicals, chemical fibers, worsted, rubber, grain, sugar, oils, fats and watches.

The marked improvement in China's foreign trade in 1979 resulted from the high importance attached by the Party and government to developing foreign trade and strengthening the leadership of foreign trade work. In July 1979, the Standing Committee of the National People's Congress adopted a resolution to establish the People's Republic of China Import and Export Management Commission to strengthen leadership and management of foreign trade. In July, August and September, the Party Central Committee and the State Council further formulated a string of important goals, policies, and measures to reform the foreign trade system and develop foreign trade, thereby bringing the enthusiasm of all quarters into full play. In the meantime, foreign trade departments shed old ideas, took a new look at international trade practices, and vigorously and selectively adopted many flexible trading methods and engaged in cooperative bargaining. This, too, was one of the main contributing factors to the marked success in foreign trade in 1979.

The Development of Foreign Trade Relations in 1979

The year 1979 was an important year in the history of development of foreign trade relations with foreign countries. During that year, China signed trade agreements with the governments of Jordan, Liberia, Tunisia, Algeria, the Philippines, Sweden, Singapore and the United States; signed a protocol with the Thai government on the long-term supply of oil from Shengli Oil Field; concluded a protocol with the government of Zaire on the supply of many commodities; and reached an agreement with Japan on extending the long-term Sino-Japanese Trade Agreement and increasing the amount of money therein provided. In July, the Chinese and U.S. governments formally signed the Sino-U.S. Trade Relationship Agreement, marking entry into a new stage in Sino-U.S. trade relations.

To strengthen economic and trade relations and scientific and technological cooperation with foreign countries, in 1979 China also signed an agreement with the Yugoslav government on mutual exemption of duties against the passengers and goods shipped between the two countries, an ocean shipping agreement with the Thai government, and air transportation agreements were concluded with Britain, Italy, Finland, the Belgian-Luxembourg Economic Union, Denmark, the Federal Republic of Germany, Burma and the United States. The Bank of China signed a development loan agreement with the Japan Export-Import Bank, and with a new governmental Japanese banking group signed a short-term trade loan protocol and an intermediate-term civil loan protocol.

Exhibitions are a good means for promoting the development of China's foreign economic and trade relations. In 1979, eight exhibitions were held by Yugoslavia, Japan, Italy, Switzerland, the German Democratic Republic, and Britain in Beijing, Shanghai, Tianjin and Wuhan. China, in turn, held economic and trade exhibitions in Bangladesh, Thailand, Yugoslavia, Congo, Argentina and Jordan, and participated in international exhibitions in Liberia, Sudan, the German Democratic Republic, Romania, France, Morocco, Yugoslavia, Zaire, Argentina, Italy, Sweden, Greece, India, and New Zealand. On 10 May 1979, China and the United States signed an agreement on holding trade exhibitions in each other's countries. According to this agreement, during the period May to October, 1980, China will hold economic and trade exhibitions in these and other cities in the United States, and the United States will hold an exhibition in Beijing in 1980, followed by other exhibitions in Beijing and other cities in China.

The Chinese Export Commodity Fair is an important place for the Chinese people to conduct friendly trading activities with the peoples of other countries in the world. Since its inauguration in the spring of 1957, the fair has been held twice a year in Guangzhou from 15 April to 15 May and from 15 October to 15 November each year. By the fall of 1979, the trade fair had been held 46 times. In 1979, the spring and autumn fairs were attended by more than 49,700 persons from more than 100 countries and regions, who concluded more than 148,300 trade contracts. Compared to that of 1978, the attendance was more than 11,300 persons greater, and the total value of transactions was 24.1 percent greater.

In developing its trade relations with other countries, China has adopted the strategic view that differentiates between countries of the First, the Second and the Third Worlds. On the principles of equality, mutual benefit and the exchange of goods to meet each other's needs, China has actively developed trade relations with the various countries, based on needs and practicabilities.

By the end of 1979, China had established and developed trade relations with more than 140 states and regions of the Third World, and had signed trade agreements with 66 states. In 1979, the trade volume between China and the states of the Third World totaled US$6.66 billion, showing an increase of 32.1 percent over that of 1978, and accounting for 22.7 percent of the total volume of foreign trade conducted by China in 1979.

In 1979, China further developed its economic and trade relations with the developed Western industrial countries, and increased its trade volume with them to US$14.74 billion, showing an increase of 40.4 percent over that of 1978, and accounting for 50.3 percent of the total volume of foreign trade in 1979. Japan and the European Common Market were the major trade partners. In March 1979, China and Japan extended and expanded their long-term trade agreement; i.e., during the period 1978 to 1990, China and Japan will each export to the other goods in the amount of US$20 to US$30 billion. In 1979, Sino-Japanese trade volume totaled US$6.7 billion, showing an increase of 39 percent over the US$4.82 billion of 1978, and accounting for about 22.9 percent of the total foreign trade volume of China in 1979. In July 1979, China initialed with the Common Market a 5-year agreement on textile products, increasing the quotas on 14 of the most sensitive products (including cotton cloth, cotton yarn and shirts). The Common Market also decided to treat China as a most favored nation [literally: "...also decided to apply the general preference system in its treatment of China..."] beginning in 1980. In 1979, the trade volume between China and the Common Market totaled US$5.06 billion, showing an increase of 54.3 percent over that of 1978.

China and the United States gradually resumed and developed their trade relations in the spirit of the Shanghai Communique jointly signed by China and the United States in 1972. The signing of the Shanghai Communique marked a major step forward toward the normalization of relations between the two countries, enabling them to resume their trade relations which had been suspended for 22 years and start again their non-governmental trade activities. While in 1973 the exchange of commercial and technical personnel between the two countries amounted only to about 700 person-trips, by 1978 this figure had increased to 4,500. The trade volume between the two countries also increased. In 1978, Chinese imports from the United States amounted to US$720 million, and exports to the United States, US$270 million. The year 1979 was an important year in the development of Sino-U.S. trade relations.

On 1 January 1979, China and the United States formally established diplomatic relations. In March, the two sides agreed to establish the Sino-U.S. Joint Economic Commission. On 7 July, the two governments formally signed the Sino-U.S. Trade Relations Agreement, marking entry into a new period in these relations. In 1979, Sino-U.S. trade volume amounted to US$2.45 billion, showing an increase of 147 percent over that of 1978, and accounting for 8.4 percent of the total foreign trade volume of China in 1979.

In 1979, the trade volume between China and the Soviet Union amounted to about US$500 million.

Reform of the Foreign Trade System

The current system of management and administration of China's foreign trade was gradually shaped and developed on the basis of the practice of state control over foreign trade. Upon its founding, New China immediately abolished all the prerogatives of imperialism in China, established the state-operated foreign trade companies, adopted the policy of utilizing, restricting and reforming the foreign trade enterprises owned by private capital, imposed state control over foreign trade, reformed the customs system, and established a system of foreign trade management and administration centering on the state-operated foreign trade companies which were under state control. In 1956, following the virtual completion of the socialist reform of the system of ownership, China had actually already achieved state monopoly control over foreign trade. Centralized leadership and unified administration of the whole of China's foreign trade were assumed by the Ministry of Foreign Trade, and all import and export business came under unified management by the state-operated specialized import and export companies subordinate to the Ministry of Foreign Trade. During the period 1956 to 1978, although some changes in this system were introduced continually according to the tasks assigned for different periods, there was little change in the foreign trade system in China in general. The existing foreign trade system gradually took shape under these historical conditions.

Following the entry of Chinese socialist revolution and construction into a new historical period, to speed up the realization of the four modernizations, it was necessary to greatly develop Chinese foreign trade. Under the existing foreign trade system, import and export operations were overly centralized and too rigidly controlled, making it impossible to achieve good coordination between industry and trade, between production and marketing, and causing dislocation in the matter of receiving foreign exchange from exports and using foreign exchange for imports on the part of the various localities, departments and enterprises concerned. There were also conflicts among the foreign trade departments, between the central and local authorities, between the ports and the interior, and between the various ports. These problems were detrimental to arousing the enthusiasm of the various departments, localities and enterprises for developing foreign trade. To do a good job in foreign trade and speed up the realization of the four modernizations, it was necessary to radically reform the prevailing foreign trade system in China.

Taking into consideration the characteristics of foreign trade and the actual foreign trade system prevailing in China, the reform of the foreign trade system should be carried out in the following manner: First and foremost, remove all restrictions where necessary to mobilize the enthusiasm of all quarters. In the meantime, it is necessary to assure central unity, including unity in policy, in planning and in dealing with foreign states. Under unified leadership, foreign trade should be administered and managed at various levels, with an independent accounting system. On 30 July 1979, it was decided at the 10th session of the Standing Committee of the Fifth National People's Congress to establish the People's Republic of China Import and Export Management Commission and the People's Republic of China Foreign Investment Administration Commission to improve the balancing of imports and exports, the balancing of foreign exchange, the work of importing new technology, and the control of foreign investments. After that, the Party Central Committee and the State Council issued a series of important documents, outlining some major policies and measures governing the reform of the foreign trade system and the development of foreign trade, as follows:

Place export commodities under the control of different levels of authorities separately, and broaden the scope of commodities handled by local authorities. Commodities under the control of central authorities should be exported by the various specialized companies subordinate to the Ministry of Foreign Trade. With the approval of the State Council, some of the commodities may be exported by other departments concerned. Commodities under the control of local authorities may be exported by provincial, municipal and autonomous regional authorities if practicable. All business belonging to local export plans and using local foreign exchange for imports may be handled by the local authorities concerned.

Broaden the authority of local authorities to handle foreign trade. The various provinces, municipalities and autonomous regions may establish specialized trading companies to export local commodities or certain particular commodities and to handle the import business for the localities concerned. These businesses should be handled at the local level and have their independent accounting and be responsible for their own profits and losses. With regard to certain special commodities, where conditions permit, joint industrial and trading companies may be established to handle their production, supply and marketing. With authorization certain ministries of the State Council may set up export commodity supply companies to handle their own commodities and participate in export negotiations and organization of delivery of these commodities. Where practicable, import-export companies handling both industrial production and trade or both agricultural production and trade may be organized under the dual leadership of the ministry responsible and the Foreign Trade Ministry.

Broaden the authority of production enterprises to participate in foreign trade. Where practicable, a production enterprise may participate in foreign trade activities or negotiate with foreign customers for trade to coordinate production with marketing.

Allow enterprises to retain a given percentage of the foreign exchange earned from exports to meet the needs of the localities, enterprises and departments concerned for importing supplies for developing production and expanding their businesses. This will bring into full play the enthusiasm of all quarters concerned. Favorable tax rates may be granted for the supplies which are imported to build up exports, in order to promote the expansion of exports.

Select certain areas of the few coastal provinces and municipalities where conditions permit to be treated as special export zones where more liberal control measures may be adopted on a trial basis. This may initially be carried out on a trial basis at Shenzhen and Zhuhai in Guangdong Province.

Furthermore, reforms may be carried out in the various provinces, municipalities and autonomous regions on the basis of their special characteristics and taking full advantage of their respective favorable conditions. The central authorities have decided to adopt a special policy and flexible measures in Guangdong and Fujian provinces with regard to their economic relations with foreign areas, and place the foreign trade business in Beijing, Tianjin and Shanghai under the dual leadership of the central and local authorities, with emphasis on the local, and with independent accounting, thus broadening the foreign trade authority of these three municipalities.

New Measures in Foreign Trade

In the past few years, on the basis of equality, mutual benefit, and mutual respect of each other's independence and sovereignty, the Chinese foreign trade companies have adopted more flexible patterns and methods in foreign trade according to the commodities, markets and trading partners concerned, to meet China's needs for expanding foreign trade during the new period, and, by means of foreign trade to draw funds more effectively from foreign countries, import more modern technology and equipment to speed up the socialist modernization program in China. In 1979, these new measures were put into practice on a much broader scale.

With regard to trading patterns, China adopted all the common practices in international trade, such as accepting orders for commodities of specified brands, allowing the buyers to give their own brand names to certain export commodities, allowing the buyers to attach their company names or symbols to the commodities alongside the Chinese brand names; processing the materials supplied by customers in to the products they need according to their suggested patterns, styles and packaging preferences; energetically setting up businesses to assembly products from parts processed abroad, processing or assembling raw materials, supplementary materials, components, primary sub-assemblies and packaging materials supplied in whole or in part by foreign businessmen into finished products to earn labor and processing charges; actively carrying out all forms of compensatory trade--repaying the funds, patented technology and advanced equipment supplied by foreign firms with products directly or indirectly, by installments or in batches; carrying out cooperative international productive operations, such as producing parts, components or complete sets of tools expressly for foreign firms to be used in producing complete sets of machinery, or cooperating with foreign firms in producing certain products, with each side marketing part of the products; and participating in joint ventures in China or abroad with foreign firms, etc.

With regard to the manners of payment, and according to actual conditions, China also mastered and put to use, flexibly, common practices in international trade. These include accepting credit from banks or governments where appropriate, in addition to continuing to use commercial credit in the field of imports; and accepting not only currently-dated letters of credit as a means of payment but also post-dated letters of credit, to provide some leeway for the buyers in order to do more business in the field of exports. In addition, China has also accepted the escrow practice to a suitable extent in transactions, although in most cases the payments must be made at the time of the completion of the transactions concerned. Also, in exporting complete sets of equipment or machines to nations of the Third World, China sometimes allows amortization in payments.

The Sino-U.S. Trade Relations Agreement

In May 1979, Juanita Kreps, U.S. Secretary of Commerce, visited China. On 14 May, she initialed the Sino-U.S. Trade Relations Agreement. On 7 July 1979, the "Agreement on Trade Relations between the People's Republic of China and the United States of America" was officially signed in Beijing by the governments of China and the United States.

The agreement provides that, to establish trade relations between the two countries on a non-discriminatory basis, both contracting parties accord the most favored nation status to each other with regard to products exported to or imported from the other country, and adopt all appropriate measures to create the best conditions for strengthening the economic and trade relations and promoting the continued and long-term development of trade between the two countries. To strive for a balance of economic interests between the two parties, the two parties will do their best to promote a mutual expansion of trade. The agreement also provides that the two parties acknowledge the important roles played by government trade organizations in developing the trade and economic relations between the two countries. The two parties agree to encourage and support these organizations in their efforts to promote trade, and according to their respective capacities, will do their best to facilitate such activities. This agreement will remain in effect for three years. Unless either contracting party informs the other of its desire to terminate this agreement at least 30 days before the expiration date, this agreement will be extended by another 3 years. It may continue to be extended in the same manner.

This agreement was approved by the Standing Committee of the National People's Congress of China and by the U.S. Congress. On 1 February 1980, the Chinese Ministry of Foreign Affairs and the U.S. Embassy in China exchanged notes in Beijing, announcing that the agreement formally took effect as of that date.

Establishment of the International Trust and Investment Company of China

The International Trust and Investment Company of China was formally established in Beijing on 4 October 1979. Its charter, approved by the State Council, states that the company is a state-operated socialist enterprise under the direct leadership of the State Council. The company will, according to the People's Republic of China Joint Venture Law and other general laws, decrees and regulations of the state, engage in guiding, absorbing and utilizing foreign funds, importing advanced technology and equipment, making construction investments in China, and accelerating construction for the socialist modernization of China. The company is capitalized at 200 million yuan in renminbi. Its main office is in Beijing. It has a branch in Hong Kong, and may establish other branches, sub-branches, offices and agents in China and abroad, according to actual needs.

At its first board of directors meeting, the company announced the namelist of members of its board of directors as approved by the State Council. The board of directors is composed of 44 persons. Rong Yiren, Lei Renmin, Wu Zhichao, Chen Shuxin, and Wang Jianshi are members of its standing committee, Rong Yiren is the chairman, and Lei Renmin the vice chairman. Rong Yiren serves as the general manager, with Lei Renmin, Wu Zhichao and Chen Shuxin ad deputy general managers. Other members of the board of directors include leaders of the various central and local departments concerned, members of the China Democratic National Construction Association, members of the All-China Federation of Industrial and Commercial Circles, representatives of industrial and commercial circles in the various localities, members of industrial and commercial circles in Hong Kong and Macao, and noted lawyers, economists and patriots, totalling 39 persons.

Joint Venture Law Promulgated

The Second Session of the Fifth National People's Congress of the People's Republic of China on 1 July 1979 adopted the "Law of the People's Republic of China on Joint Ventures Using Chinese and Foreign Investments." This law has 15 articles, clearly setting forth the rights and interests of the participants in joint ventures.

The law provides the following: With a view to expanding international economic cooperation and technological exchange, China permits foreign companies, enterprises, other economic entities or individuals to incorporate themselves, within the territory of China, into joint ventures with Chinese companies, enterprises or other economic entities on the principle of equality and mutual benefit and subject to authorization by the Chinese government. The Chinese government protects, by the legislation in force, the resources invested by a foreign participant in a joint venture and the profits due him pursuant to the agreements, contracts and articles of association authorized by the Chinese government as well as his other lawful rights and interests. All the activities of a joint venture shall be governed by the laws, decrees and pertinent rules and regulations of China. A joint venture shall apply to the Foreign Investment Control Commission of the People's Republic of China for examination and approval of the agreements and contracts concluded between the parties to the venture formulated by them. After approval, the joint venture shall register with the Industry and Commerce Administration and Management General Bureau of the People's Republic of China and receive an operating license. A joint venture shall take the form of a limited liability company. The foreign participant's share of investment in a joint enterprise shall generally not be less than 25 percent of the venture's registered capitalization. Each party to a joint venture may contribute cash, capital goods, industrial property rights, etc. as its investment in the venture. The technology or equipment contributed by any foreign participant as investment shall be truly advanced and appropriate to China's needs. The investment contributed by a Chinese participant may include the right to the use of a site provided for the joint venture during the period of its operation. A joint venture shall have a board of directors whose chairman is appointed by the Chinese participant and the vice chairman by the foreign participant. The board of directors deals with major questions through consultations before decision, on the principle of equality and mutual benefit. The general manager and assistant general manager shall be chosen from the various parties to the joint venture. The net profit which a foreign participant receives as his share after executing his obligations under the pertinent laws and stipulations of agreements and contracts, the funds he received at the time when the joint venture terminates or winds up its operations, and his other funds may be remitted abroad through the Bank of China in accordance with the foreign exchange control regulations and in the currency or currencies specified in the contracts concerning the joint venture. The wages, salaries or other legitimate income earned by a foreign worker or staff member of a joint venture, after payment of the personal income tax under the tax laws of the People's Republic of China, may also be remitted abroad through the Bank of China in accordance with the foreign exchange control regulations. The law also has provisions governing the joint ventures' production arrangements, product marketing arrangements, organizations, personnel allocations, limits of management authority, contract durations and settlement of disputes.

Special Policies and Flexible Measures Applicable to Guangdong and Fujian in Their Foreign Economic Activities

The Party and government have decided that, within the framework of the uniform foreign trade goals, policies and plans of the state, Guangdong and Fujian Provinces may make their own arrangements for foreign trade according to their particular conditions to meet the needs of developing their foreign economic activities and speeding up their socialist modernization and construction. Their provincial foreign trade company branches are now under the dual leadership of the provincial authorities and the companies' main national offices. The two provinces may conduct their own import and export business; the products they export and import will not be subject to the limitations currently in effect regarding a division of labor by port and commodity. They may also establish on a trial basis specialized companies subordinate to their provincial governments to handle the production, domestic marketing and export business for certain export products, according to the principle of coordinating production with marketing, industry with trade, and domestic with foreign trade. With regard to commodities whose exportation is regulated by given quotas, overall arrangements should be made by the Ministry of Foreign Trade to grant more liberal quotas to Fujian Province. Each of the two provinces may decide on the prices it will pay for commodities it imports with its own foreign exchange. In foreign trade activities, the Ministry of Foreign Trade must remain in charge of arrangements with different countries (and areas) so as to maintain control over the prices of a few commodities which are imported or exported in large quantities and for which the monopolistic nature of the international market is strong and/or competition is fierce. Guangdong Province is setting up special export zones on a trial basis. Within these zones, it is permissible for Overseas Chinese, Hong Kong, Macao, and foreign firms to invest in the establishment of plants or to participate in joint ventures, tourist facilities, or other undertakings. The principle of administration in the special zones shall be: that China's sovereignty must be upheld, that China's laws and decrees must be enforced, and that China's foreign exchange controls and customs system must be observed on the one hand; but that--in economics--a policy of lifting restrictions must be implemented on the other. Accordingly, foreign investers and plant managers are protected by the laws of China; favorable tax rates are granted to the import of needed supplies and export of commodities from these special zones; foreign investers are allowed to remit their legitimate profits abroad after paying all taxes in accordance with related rules and regulations; and arrangements for people entering and department from these zones are simplified. The special zones will have customs, commodity examination, quarantine, frontier inspection, banking, postal and telecommunications facilities. In Fujian province, the Fujian Provincial Investment Enterprise Company is established as a consolidated enterprise with independent accounting, assuming sole responsibility for its own profits and losses. Under the leadership of the Fujian People's Government, it is engaged in such foreign business activities as inviting investments from Overseas Chinese and foreign capital, importing advanced technology and equipment and establishing enterprises, in accordance with the appropriate provisions of the state. The company will handle the export of the products produced by its enterprises, the foreign exchange earned therefrom, and the payment of expenditures according to an overall plan.

Foreign Trade in Beijing, Tianjin and Shanghai Is Under the Dual Leadership of the Foreign Trade Ministry and the Municipal Government Concerned, With Greater Emphasis on the Latter

Beijing, Tianjin and Shanghai are three important industrial bases of China, noted for their textile and light industry, their traditional handicraft products, and their fast-developing electronic, instruments, petroleum, and chemical industries. Their coastal location affords them excellent conditions for developing foreign trade. To study how to bring the advantages of the three cities into full play and how to adopt effective measures to increase exports and earn more foreign exchange, in August 1979 the Central Import-Export Control Commission convened in Beijing a Beijing-Tianjin-Shanghai export business symposium. The symposium made the following suggestions to reform the prevailing foreign trade system and grant greater authority to the three cities in handling their foreign trade, according to the guidelines of the central authorities and taking into consideration the particular conditions of the three cities themselves. These suggestions were approved by the State Council on 14 September 1979 for implementation.

Under the guidance of the unified foreign trade goals, policies and plants of the central authorities, foreign trade business in Beijing, Tianjin and Shanghai is to be under the dual leadership of the Ministry of Foreign Trade and the three city governments concerned, with greater emphasis on the latter. Each city will establish a municipal import-export company which is under the dual leadership of the Ministry of Foreign Trade and the city government concerned, with greater emphasis on the latter. Branches of each municipal import-export company are under the dual leadership of the Import-Export Corporation of the Ministry of Foreign Trade and their respective municipal import-export company, with greater emphasis on the latter. Each of the municipal import-export companies and their branches has its own independent accounting system.

Each city will formulate and readjust its plans for the procurement of commodities for export and the accumulation of foreign exchange from exports according to the needs of the world market and according to the principle of setting production targets in accordance with market conditions. The export of commodities under the control of central authorities is to be determined jointly by the State Planning Commission, the Foreign Trade Ministry and the ministries concerned. The export of commodities under municipal control may be arranged by the city government concerned according to the supply situation. For both centrally-controlled and locally-controlled commodities, each city may on its own increase production and efforts, with the proviso that it be able to meet raw materials needs. The import outside plan of commodities which can facilitate the export of other commodities may be carried out by city authorities themselves, within previously arranged foreign exchange limits, without reporting each case to higher authorities for approval.

Trade in important goods which are imported and exported in large quantities and intergovernmental trade should still be negotiated and agreed to by the Ministry of Foreign Trade and the national office of the various specialized import and export corporations on the basis of unified discussions with the foreign parties, and be carried out by the city branches of these corporations. The city branches may directly handle the import and export of other commodities, wothout being restricted by the specialized import and export quotas assigned to the various sea ports.

The Composition of China's Import and Export Commodities

I. Composition of Export Commodities

Year	Export Volume (in US$ million)			Export Volume (in %)		
	Agricultural & Subsidiary Products	Processed Agricultural & Subsidiary Products	Industrial & Mining Products	Agricultural & Subsidiary Products	Processed Agricultural & Subsidiary Products	Industrial & Mining Products
1950	318	183	51	57.5	33.2	9.3
1952	488	188	147	59.3	22.8	17.9
1978	2,691	3,414	3,640	27.6	35.0	37.4
1979	3,157	4,486	6,014	23.1	32.9	44.0

II. Composition of Import Commodities

Year	Import Volume (in US$ million)		Import Volume (in %)	
	Capital Goods	Consumer Goods	Capital Goods	Consumer Goods
1950	486	97	83.4	16.6
1952	999	119	89.4	10.6
1978	8,864	2,029	81.4	18.6
1979	12,747	2,928	81.3	18.7

Total Volume of China's Foreign Trade
(in US$ billion)

	1950	1952	1978	1979		
				Total Volume	Increase over 1978 (%)	Taking 1950 as 100
Total Trade	4.15	6.46	35.50	45.46	28.1	1,095.4
Total Imports	2.13	3.75	18.74	24.29	29.6	1,140.4
Total Exports	2.02	2.71	16.76	21.17	26.3	1,048.0

Domestic Commerce

[Article by Su Xuesheng [5685 1331 3932--The author's name may be translated literally as "Soviet Student"]]

In 1979, Chinese commercial departments achieved marked successes in serving the interests of industrial and agricultural production and the livelihood of the people, while adhering to the policy of readjusting, restructuring, consolidating and improving the national economy and carrying out the principle of "developing the economy to assure supplies."

There were abundant supplies in urban and rural markets to guarantee satisfaction of the basic livelihood needs of the people. In 1979, the total volume of retail sales of social commodities in China was 14.7 percent higher than that of 1978, that of commodities in cities was 16.8 percent higher, and that of commodities in counties and lesser administrative units 11.6 percent higher, of which that in administrative units below the county level 13.3 percent higher. The sales volumes of major consumer goods--foodstuffs, clothing, daily necessities, fuel--showed an overall increase. There was a marked improvement in the supply of food items. The total sales volume of ten items--grain, edible oil, meat, eggs, aquatic products, sugar, tobacco, liquor, salt, and caustic soda--showed an increase of 12.6 percent over that of 1978, and that of pork, in particular, showed an increase of 25 percent. In hog-producing areas and in Beijing, Tianjin, Shanghai and other municipalities, pork was obtainable without rationing. The supply and variety of candies, cakes, spirits and delicatessen items also increased. The market conditions for clothing were also excellent. The sales volume of 10 major commodities including cloth, knitwear, cotton textiles, and rubber shoes increased by 16.2 percent over that of 1978. Retail sales of cotton cloth and chemical fiber cloth increased by 850 million meters, averaging 2.7 chi [.9 meters] per capita, after guaranteeing the requirements for rationed cloth. The sales volumes of all kinds of woolen piece goods, knitting wool, silk piece goods, bed covers, and leather shoes showed substantial increases, too. Sales volumes of daily necessities showed substantial increases, too. Sales volumes of daily necessities showed faster increases over 1978. Sales of bicycles, sewing machines, radio sets, and watches showed increases of from 18 to 40 percent; of soap, 15 percent; laundry detergent, 7.6 percent; thermos bottles, 9 percent; television sets 200 percent, and tape recorders 300 percent. As for fuels for home use the sales volume of coal and kerosene was 3.8 percent higher. In 1979, supplies of industrial products were noted not only for their larger quantity, higher quality, and greater variety, but also for a large number of new products, such as refrigerators, electronic watches, electronic calculators, electric razors, induction fans, calendar watches, multi-purpose sewing machines, multi-speed bicycles, plastic carpets and coarse woolen piece goods.

Following the development of industrial and agricultural production, the supply of commodities increased by a large margin, and the commercial departments increased the purchase of industrial and agricultural products, thus promoting the further development of industrial and agricultural production. In 1979, the total volume of commodities purchased by state-operated commercial units showed an increase of 14 percent over that of 1978. The total volume of agricultural and subsidiary products purchased amounted to 58.68 billion yuan, or 27.6 percent greater than that of 1978. The purchase volumes of such major agricultural and subsidiary products as grain, edible oil, poultry, eggs, silk, tea, wool, apples, and oranges were all greater than those of 1978. The purchase volume of live hogs was 29 percent greater. The average weight of each live hog purchased was 12.1 jin greater, cumulatively equaling an additional 10 million hogs purchased, resulting in overfulfillment of planned allocations for that purpose by 75 percent. The volume of fresh eggs purchased was 49.8 percent greater. Thanks to the measures adopted by the state to promote the development of the textile and light industries, purchases of industrial products increased at a relatively fast speed. The total amount of industrial products purchased in 1979 amounted to 140.56 billion yuan, showing an increase of 9.8 percent over that of 1978. Within this figure, purchases of industrial products processed from industrial and mining raw materials were 13.1 percent greater, and of those processed from agricultural and subsidiary products, 5.3 percent greater. The purchase volumes of 34 of the 42 major industrial products showed increases over those of 1978. Sales of television sets, which were in greatest demand, increased by more than 100 percent, while sales of bicycles, sewing machines, watches, and radio sets by from 7 to 17 percent.

The remarkable increases in the purchases of industrial, agricultural and subsidiary products contributed to a rather large increase in inventory and an improvement in the composition of inventory. By the end of 1979, the total inventory kept by state-operated commerce was 11.6 percent greater than that at the end of 1978. The percentage of inventory kept by second-level wholesale stations and third-level wholesale stores diminished a little, while that of retail units increased to some extent. Along with the increasing inventories of major commodities, the percentage of inventory of the most popular regular commodities increased from the 84.7 percent in 1978 to 88.7 percent in 1979, reflecting a turn for the better in the composition of commodity inventories.

Building on the continual expansion of commodity circulation, there was a strengthening in construction in the commercial network itself. In 1979, large numbers of sales outlets and warehouses were built across the nation, and additional freight vehicles and vessels, of both general and specialized use, were made available to this network. In addition, a number of modern warehouses, oil storage tanks, refrigeration warehouses, and thermostatically controlled vegetable warehouses were the focus of construction in large cities and commodity collection and distribution centers. Some of them also adopted advanced management techniques to administer their systems. Preliminary statistics show that in 1979, China increased its state-operated sales outlets by more than 10,000. At the same time, a large number of collectively-operated sales units and restaurants came into being, with collective commercial outlets now amounting to 30-40 percent as many as state-operated retail sales units. In 1979, more than 120 refrigeration warehouses, large, medium and small, were completed and put into operation, with a total refrigerating capacity of more than 100,000 tons, topping the refrigeration warehouse construction of any other year in the past ten or more years. These warehouses greatly increased the capacity of the state to keep beef, mutton, pork, poultry and fresh eggs in cold storage, thus playing an important role in promoting the development of industrial and agricultural production and increasing the supply of meat and eggs to cities.

In 1979, there was great improvement in the management and administration of commerce, and good results were achieved in the campaign to increase production and practice economy. During that year, the broad masses of workers and staff employees in the system under the Ministry of Commerce universally participated in this campaign to promote production, expand commodity circulation, improve management, and increase accumulation, in line with demands from party and government. Many areas adopted measures to simplify redundancies in their organizations, reduce the number of transshipment points in goods circulation, and brought about greater use of direct-line transportation. As a result, they cut short transportation mileage by more than 1.6 million kilometers in 1979, saved more than 300 million ton-kilometers of shipping capacity and more than 200 million yuan in transportation expenditures. [The "300 million ton-kilometers" figure is given literally as "3 trillion" in the original, but there appears to be a typographical error--an extra "wan"--that throws the figure off by a factor of 10,000.] Many areas also adopted measures to accelerate capital turnover and reduce commodity circulation expenses. In 1979, capital turnover was shortened by 22 days as compared with that of 1978, the level of expenditures dropped 0.86 percent, and the amount of profits handed over to the state was 13 percent greater. Many enterprises relentlessly stressed the practice of economy and the unearthing of latent energy. In 1979, more than 2,000 enterprises switched their deficits into profits. Among those enterprises which still suffered from deficits, their total deficits were reduced by 26 percent. Some of the enterprises managed to markedly reduce their deficits which were allowed by the state as a matter of policy. During the campaign for increasing production and practicing economy and the labor emulation drive, many advanced units and individuals emerged in the system under the Ministry of Commerce. In 1979, 24 units were named national advanced units, and 32 individuals were named national labor models by the State Council; 50 units were named New Long March commando brigades and 350 individuals New Long March shock workers by the Central Committee of the Communist Youth League; and 36 units were named red flag collectives and 417 individuals "March 8th" red flag pacesetters by the All-China Federation of Women.

Close Industry-Commerce Coordination

The relationship between industry and commerce in China is a new form of relationship of coordinated division of labor founded on the system of public ownership. Under the guidance of the state policy of readjusting, restructuring, consolidating and improving the national economy, through close coordination, mutual support and mutual promotion, industrial production showed quick development and commercial operations achieved continual expansion, which has brought a great improvement in the relationship between industry and commerce.

Under the new policy of regulating the economy both by planning and by market conditions, the development of industry was more oriented toward serving the interests of market. Commercial authorities were more eager to reflect to the industrial authorities the demands of consumers, offering to assist them in the readjustment of certain enterprises and the reshuffling of their products. A number of enterprises whose products were of poor quality and high-priced and whose operations were at a deficit, and a number of small plastics, tobacco, and fur-processing factories which competed with big plants in raw material consumption were closed, suspended, amalgamated and converted. A number of new plants were built to produce commodities in urgent need. Military industrial units and heavy industrial units were assisted to produce, some on a trial basis, such civilian products as refrigerators, motor cars, and washing machines. Old plants were encouraged to develop their potentials and undergo renovation to produce commodities of attractive new design at reasonable prices.

Following the readjustment of industrial and commercial enterprises, their products were more in keeping with market demands. The state increased its purchase of popular commodities which were in short supply. In 1979, the purchase volumes of such commodities as soap, electric bulbs, leather shoes and bicycles were more than 10 percent greater than in 1978, purchases of polyester and chemical fabric, which are in popular demand, were 20 and 40 percent greater, respectively, and purchases of television sets and tape recorders were more than 100 percent greater. The number of new products produced, some on a trial basis, in 1979 topped that of any previous year. More than 3,000 new products were placed on exhibition in the National Light Industry New Products Exhibition. This greatly enriched the supply of commodities on the market.

Keeping in pace with the development of production, the commercial authorities restored and established a commodity examination system, and changed their indifferent attitude of early 1979 toward the purchase of industrial products. All storable commodities for which the price matched the quality, but which were temporarily overstocked were purchased, placed in storage as needed and actively marketed. Thanks to the joint efforts of both industrial and commercial authorities, the total amount of industrial products purchased in 1979 was 9.8 percent greater than in 1978.

Some improvement was achieved in the commodity marketing system, on the basis of the development of production, to bring the role of market conditions as regulator of the economy into full play. For many years, industrial products had been under the rigid control of commercial wholesale departments which monopolized their marketing. To change this situation, and according to different conditions for commodities in categories 1, 2 and 3, industry-commerce links were broadened from the single method of state monopoly purchasing and sole-agent marketing to an experimental use of many methods, such as: state monopoly purchasing and marketing; planned purchasing; purchasing by prior orders; purchasing by free choice; commissioning of commercial agents by industries to sell on commission; or to sell as agents of the industries; marketing through direct links between factory and retail outlet; or marketing by the plants themselves. In Tianjin, Shanghai, Wuhan and some other cities, wholesale markets for sundry commodities were restored to facilitate transactions between industrial and commercial units as well as between wholesalers and retailers. After its restoration for two months, the Wuhan sundry commodity wholesale market was attended by dealers from more than 10 provinces, with a total volume of transaction amounting to 2 million yuan, covering 2,652 types of commodities. The supply and marketing cooperatives in China opened more than 600 warehouses to engage in buying, selling, storing and transporting agricultural and subsidiary products, industrial raw materials, and sundry industrial products on consignment for enterprises, communes and production brigades and teams. Many provinces and municipalities also authorized the restoration of consignment companies and sales departments operated by industrial plants. Industrial and commercial units gradually returned to the production-and-marketing contract system according to state plans. Large numbers of trade fairs were held throughout China. In Chongqing, Ningbo, Jinan, Foshan and some other cities, industrial and commercial enterprises held joint symposiums to study the demands of consumers, exchange views between producers and sellers, achieve unity in opinions, eliminate disputes in procurement and marketing, and establish closer relationships. All these measures were beneficial to the development of production, the expansion of trade between urban and rural areas, the improvement of marketing conditions, and the promotion of more active and better transactions.

Urban Collective Commerce

Urban collective commerce and services are elements of the economy under collective ownership, with a socialist character. They are noted for their independent accounting, for taking sole responsibility for their profits and losses, for greater autonomy and flexibility in their operations, for their wide dispersion throughout the country, for their smaller scale in business operations, and for their ability to meet the convenience of the people. The development of collectively-owned commerce is in keeping with present economic conditions in China and with the popular demands of the broad masses of the people.

In 1957, there were 790,000 urban collective commercial units, large and small, in China, accounting for two-thirds of the retail and service units controlled by the Ministry of Commerce, and employing 1.98 million staff personnel and workers, or 45.5 percent of all employees in retail commerce and services controlled by the Commerce Ministry. Nevertheless, over a long period of time, the number of collective commercial units not only failed to increase but substantially decreased. By 1964, their number had diminished by 62 percent to 300,000, and their employees by 30 percent to 1.35 million. During the period of the cultural revolution, due to the interference and sabotage of Lin Biao and the "gang of four," the number of collective commercial units was further cut down in the name of "cutting off the tail of capitalism." Compared to the figures in 1964, their number further diminished by 80 percent to 60,000, and their employees by 40 percent to a little over 800,000. After the "gang of four" was smashed, the state adopted a series of measures to develop collective commerce. In 1979, the State Council and other related authorities affirmed that collective commercial units are socialist in nature, and clarified many problems demanding urgent solution for the development of collective commerce, such as the organization of their trade unions, the wages and welfare of their employees, their ways and means to get supplies, and the distribution of such supplies. With the support of urban neighborhood committees, industrial and mining enterprises and state-operated commerce, large numbers of collective-operated restaurants, wineshops, hotels, tea houses, barber shops, photo shops, sewing shops and repair shops mushroomed. According to incomplete statistics compiled in 24 provinces, municipalities and autonomous regions, by the end of 1979 the number of collective-operated commercial units had been restored to 99,000, equal to 44 percent of the retail commercial and service units under the control of the Ministry of Commerce in these provinces, municipalities and autonomous regions, and employment had rebounded to 1.04 million staff personnel and workers, equal to 38.9 percent of the workers and staff in the above-mentioned Ministry-run retail units.

The development of the collective-commerce is playing an increasingly important role in promoting production, invigorating market conditions, expanding the commercial network, providing more convenience to the masses, and increasing the employment of the unemployed young people.

[Article by Wang Shaoquan [3076 4801 6898]]

The Development of Urban Food and Drink Services

Food and drink services are closely bound up with the daily livelihood of the broad masses of the people. At the time when Lin Biao and the "gang of four" were running wild, these facilities were devastated. This category of enterprises was thrown out of shape and out of style, with both their numbers and their professionalism seriously reduced, causing great inconvenience to the masses. Since the smashing of the "gang of four" and, particularly, since 1979, a network of such facilities has sprung up with new vigor, adding new service items, restoring traditional food items, training new personnel, and paying their employees according to the principle "to each according to his work."

The number of restaurants and service units has grown rapidly, with mostly small and collective-operated units equipped with the simplest of equipment, with both street vendors and shops and distributed in a rational pattern. According to incomplete statistics, in 1979 there were 72,000 urban food and drink service units, large and small, under the control of the commercial departments, showing an increase of 4.1 percent over 1978. These facilities employed a total of about 1,295,000 workers and staff, an increase of 6.9 percent. In addition, large numbers of restaurants and service units under collective ownership mushroomed on urban streets, offering employment to large numbers of unemployed young people.

Through the study of actual conditions, such as the size of these facilities, their type of customers, their equipment, manpower and location, many localities managed to expand the network of these facilities, increase their types of services, restore their traditional items, and bring their specialties into full play. In Shanghai, for instance, state-operated food and drink establishments again began offering 600 specialty menu items. Some localities also developed tourism, organizing special tours to scenic areas and historic sites to enrich the lives of the people and open a new way to recall currency from circulation without commodities.

To solve the problem concerning the critical shortage of technically trained personnel, the various localities opened training schools and classes, promoted on-the-job training and apprenticeships, and conducted technical examinations to provide trained personnel to restaurants and service units. Statistics compiled in 23 provinces, municipalities and autonomous regions show that during 1978 and 1979, the various localities awarded the titles of special class and first class cooks, barbers, photographers, pedicurists, dyeing technicians, clothes mending technicians, and service specialists to 443 persons according to the "Criteria for Grading Professional and Technical Personnel of Commercial Enterprises" promulgated by the Ministry of Commerce and with the approval of the revolutionary committees of the various provinces, municipalities and autonomous regions concerned. Thanks to the training programs and the awarding of titles, not only were traditional techniques continued and improved, but the quality of services of restaurants and service units was markedly improved also.

To carry forward the principle "to each according to his work" and bring into full play the work enthusiasm of staff personnel and workers, beginning in 1978 the barber shops began to adopt the system of paying bonuses over and above the basic pay to barbers who overfulfilled their work quotas. In 1979, this system was adopted by other trades too. In some cases, the amount of each bonus was calculated on the basis of a given percentage of total profits, in other cases the bonus was based on the amount of profit earned from the overfulfilled portion of one's work quota, and in still others it based on a combination of the two. This practice enabled the state to gain more profits, the workers concerned to increase their income, the customers to save time, and the enterprises to accumulate more funds for improving their service conditions.

Organize the Circulation of Commodities According to Economic Zones

It is one of the important principles of socialist commerce to organize the circulation of commodities according to economic zones. In the 1950s and, particularly, in the early 1960s, commercial authorities in China earnestly popularized the experiences gained by the Tangshan prefecture of Hebei Province in organizing the circulation of commodities according to economic zones, and many localities succeeded in establishing their wholesale commodity circulation networks accordingly. During the great cultural revolution, however, due to the interference and sabotage of Lin Biao and the "gang of four," many localities changed their practice of organizing the circulation of commodities according to economic zones to doing so according to administrative areas, resulting in overlapping control organs, unnecessary transshipments, dispersion of inventory, unnecessary detours in transportation, and greater expenditure in commodity circulation.

After the "gang of four" was smashed, the various localities started to pay attention to the restoration of the practice of organizing commodity circulation according to economic zones. In October 1979, the State Council approved a report of the Ministry of Commerce on its suggestions for improving commercial work, and reiterated the need to "rearrange the locations of second-level wholesale stations according to economic zones." Thereupon, the Commerce Ministry issued the "Notice Concerning the Relocation of Second-Level Wholesale Stations to Improve Wholesale Networks," demanding that second-level wholesale stations be rearranged and relocated according to economic zones, that such stations be situated in cities serving as production centers and hubs of transportation, that the sphere of supply of a second-level wholesale station be delimited by rational commodity circulation routes, not determined by the division of administrative areas, that overlapping wholesale organizations be streamlined, that unnecessary transshipment links be eliminated, that each zone be served by one set of wholesale supply units according to the practice of conducting rational commodity circulation, that the supply of commodities be carried out strictly according to economic zones, cutting across administrative areas, and that transportation lines be selected so that they are as direct as possible and as close to the plants, railway stations, wharves and warehouses concerned as possible.

In 1979, a total of 51 second-level wholesale stations and 132 third-level wholesale outlets were relocated, eliminated or amalgamated according to economic zones, the number of transshipments in commodity circulation within an economic zone was reduced by one or two or three, and irrational transportation lines were rearranged, saving more than 200 million yuan in transportation expenses, shortening transportation mileage by more than 1.6 million kilometers, saving transportation volume by more than 300 million ton-kilometers, and saving transportation labor by more than 4 million man-days. In Hunan, the whole province was divided into eight economic zones on the basis of the economic and communications conditions in that province, enabling it to eliminate six second-level wholesale stations, and to eliminate or amalgamate 29 overlapping wholesale organs. In rearranging and relocating wholesale stations according to economic zones, Heilongjiang province reduced the number of second-level wholesale stations from the 52 in the past to 24, reducing their workers and staff from the 7,000-odd in the past to a little over 5,200 reduced the number of transshipment points so that the amount of funds taken up by commodities in transshipment was reduced from the 30-50 percent in the past to about 10 percent, reduced the amount of commodity inventories by more than 30 percent, increased the proportion of commodities of popular demand in stock, and reduced the amount of overstocked commodities from the 11 percent in the past to 8 percent. As a result, commodity circulation in Heilongjiang was carried out with reduced mileage, in shorter time, with a lower number of transshipments, with minimum losses on the way, and at less expense.

Increase the Purchase Prices of 18 Agricultural and Subsidiary Products

(See the section: Agriculture--Raise the Purchase Prices of Agricultural and Subsidiary Products)

[Article by Jiang Huiying [5592 1979 5391]]

Raise the Selling Prices of Eight Non-staple Food Items

In March 1979, following the rise in the purchase prices of principal agricultural and subsidiary products, a development occurred where the selling prices of certain products fell below their purchase prices. To reverse this abnormality detrimental to certain enterprises, promote the development of production, stabilize market conditions, bring into full play the work enthusiasm of commercial units in their operations, stop the backward flow of supplies from urban to rural areas, and make it impossible for opportunists and profiteers to benefit by it, the CCP Central Committee and the State Council issued a joint circular, announcing that from 1 November 1979 the selling prices of eight major non-staple food items including pork, beef, mutton, poultry, eggs, vegetables, aquatic products, and milk, and all other consumer goods using these eight food items as raw materials. Specifically, on the basis of their prices in 1978, the selling price of pork was raised by 33 percent, that of fresh eggs 32 percent, of aquatic products 33 percent, and of beef and mutton, basically the same as pork in money terms. The selling prices of vegetables would be under strict control, with little or no increase. The selling prices of poultry and milk would be readjusted upward as appropriate by local authorities according to concrete local conditions and be subjected to strict control.

To compensate for the increase in expenditure caused by this normal increase in the prices of some of the non-staple food items, the state granted some subsidies to workers and staff (including retired staff employees and workers and apprentices), and adopted a string of important policies and measures to assure the stability of the prices in urban areas of such basic daily necessities as grain, edible oil, and cotton, increase the wages of some employees, readjust the wage differentials among different localities, issue additional bonuses, increase employment, strengthen price control and prohibit unauthorized increases of prices. After much work was done by authorities concerned, the market conditions in general were good and the supply of non-staple food items, in particular, showed marked improvement.

The Development of the Advertising Business

Since the founding of the New China, on the basis of reforming the old advertising business, commercial departments gradually gave form to a socialist advertising business. Nevertheless, due to their failure to realize the functions and scope of advertising in a socialist society, these authorities did not develop it at a fast rate. During the period when the "gang of four" was running wild, advertising was slandered as the sinister trash of revisionism and was seriously undermined. After the "gang of four" was smashed, the state advanced the policy of "regulating the economy simultaneously by planning and by market conditions" and paid more attention to the law of value, thereby paving the way for the restoration and development of the advertising business. Since 1979, many localities have quickly developed their advertising operations. Advertising companies have been established in 12 provinces, municipalities and regions, including Beijing and Shanghai, to handle advertising business at home and abroad. All kinds of advertisements began to appear on busy city streets and in shops, parks and sports grounds. In addition, advertisements were carried in central and local radio and television programs, newspapers and periodicals. By now, there are more advertisements and of more types than ever before since the founding of the New China.

Socialist advertising can play a positive role in promoting the interests of industrial and agricultural production, consumers, commodity circulation and international trade. Oftentimes when a new product was produced by a factory, there was a poor market for it, because the consumers were unaware of its use, properties, and characteristics. Through advertising, it could become an item of popular demand. There were many such cases in 1979. From now on, in line with the development of our national economy, the continuous expansion of social commodity circulation, the continual appearance of new products of new patterns and new varieties, and the day-by-day strengthening of China's international economic contacts, there is great potential for the development of the advertising business in China.

Total Retail Sales of Social Commodities in China

	Absolute Figures (in billion yuan)			Increase Over Previous Year		
Year	Total Retail Sales of Social Commodities	Consumer Goods	Agricultural Capital Goods	Total Retail Sales of Social Commodities (%)	Consumer Goods (%)	Agricultural Capital Goods (%)

Note: 1/ Grain in trade
2/ Includes oil seeds in oil equivalent
3/ Includes fresh pork, frozen pork, and pork products

Goods and Materials

[Article by Wu Zhong [0124 0022]]

Supply Situation for Major Domestic Goods Under Unified Allocation

In keeping with the needs of a socialist planned economy, and in implementation of unified planning with administration at different levels, the means of production in China's industry (generally termed "goods and materials") are divided into three categories: unified allocation by the state (256 types), administration at the ministry level (581 types), and local administration (7.560 types in Shanghai, for example). Goods coming under unified allocation by the state include fuels, principal raw materials and important equipment. To fulfill state contracts for the supply of these goods is a matter of great importance toward the fulfillment of the entire national economic plan.

The year 1979 was the best in the past dozen or so years in the fulfillment of state contracts for the supply of goods of the first category. Statistics show that for 41 major goods and materials under state control for unified allocation, contracts for the supply of the following 18 types of goods were fulfilled 99 percent or more (amount actually supplied, as a proportion of the amount contracted to be supplied): steel products, copper, aluminum, lead, zinc, copper products, aluminum products, lead products, pig iron, coal, sulphuric acid, concentrated nitric acid, soda ash, rubber, timber, road rollers, rubber-tired cranes, and jack hammers; contracts for the supply of the following 17 types of goods were fulfilled from 95 to 99 percent: cement, caustic soda, motor vehicles, bulldozers, belt conveyers, excavators, ore loading machines, hoists, electric bridge cranes, truck cranes, air compressors, gas separators, refrigerators, metal cutting lathes, electric cables, bare copper wire, copper trolleycar wire, and internal combustion generators; contracts for the supply of the following four types of goods were fulfilled from 90 to 95 percent: crushing machines, grinding machines, forging machines, and industrial boilers; and contracts for the supply of only the following two types of goods were fulfilled less than 90 percent: ore dressing machines and electric locomotives for industry and mining with a capacity of 80 or more tons.

Compared with the figures for 1978, the supply of 34 of the above-mentioned 41 goods showed increases. For instance, the actual supply of steel products fulfilled 99.4 percent of the total amount in state contracts, with the amount supplied showing an increase of 9.1 percent over that of 1978. In particular, that of such products in short supply as small shaped steel, wire rods, and welded steel tubing showed increases of about 20 percent. Of the 28 key iron and steel enterprises in China, 18 fulfilled their supply contracts with the state. The actual supply of timber overfulfilled the total called for by state contracts by 4.8 percent, showing an increase of 2.1 percent over 1978. Of the 15 timber-producing provinces and autonomous regions in China, 13 fulfilled their timber supply contracts with the state. The actual supply of coal by collieries under the unified allocation authority of the state fulfilled 99.1 percent of coal supply contracts with the state, showing an increase of 4.2 percent over that of 1978. The average ash and rock content of all commodity coal supplied by collieries under unified allocation diminished by 1.12 percent from 1978 levels, equaling in value the supply of an additional 4 million tons of coal to the state. In addition, the supply of seven kinds of motor-driven and electric machinery, including motor vehicles and belt conveyors, showed increases of from 30 to 70 percent as compared to 1978 figures.

The Structure of Management and Administration for Goods and Materials and the Construction of Supply Networks and Units

China's goods management structure is now in the process of rapid restoration. By 1979, the 29 provinces, municipalities and autonomous regions had completely restored and reinforced their material supply bureaus and their subordinate specialized management corporations. There were 19,500 comprehensive and specialized supply networks and units for all kinds of materials under the control of the material supply departments at all levels in the various provinces, municipalities, autonomous regions, prefectures, cities and counties. Of this number, 5,800 were in urban areas and 13,600 in rural areas, employing 23,000 full-time and part-time service workers for servicing their supplies in factories, farms, and private households.

The General Office of the State Supplies Bureau has established the following nine national specialized general corporations: The China Metal Materials Company, China Fuel Company, No.1 Motor-Driven and Electric Equipment Company, No.2 Motor-Driven and Electric Equipment Company, China Timber Company, China Chemical Engineering Company, China Metal Reclamation Company, China Moving and Storage Company, and China Container Transportation Company, restored its five branch offices in Shenyang, Tianjin, Wuhan, Xi'an and Chengdu, and established coal allocation and shipping teams and stations at 50 major coal mining bureaus distributed in 11 major coal-producing provinces. Adopting such modi operandi as joint operations with local specialized companies, commissioning local companies to act as agents, and setting up supply stations under direct central control, these specialized companies established a large number of supply networks and units responsible for supplying materials to enterprises under the direct control of the central authorities.

The State Supplies Bureau head office requested the material supply departments at the various levels and the specialized companies to formulate plans for completing the establishment of a sound, comprehensive national material supply network in 2 or 3 years.

[Article by Wu Zhong [0124 0022]]

Ways and Means To Improve the Supply of Materials

Acting in accordance with the principle of reforming the economic system decided on by the CCP Central Committee and the State Council, and while they were in the midst of studying and formulating a plan for the reform of the materials supply management system, the materials supply departments at all levels have been exerting themselves to improve their management and to meet the call to handle economic work and materials supply in a livelier manner. To overcome as quickly as possible the malpractice of over-rigid controls for applying from one level to another for the allocation of materials, with the resultant poor linkage among supply, production, and marketing, they advanced many flexible methods of handling the planned allocation of materials, the major of which include the following:

Allow the users to place orders for materials, within their total allotted quota, according to their needs. One way to do so is not for the suppliers to issue control figures limiting supplies item by item, but to allow the user to submit a list of the supplies he needs, complete with their specifications (such as in the case of steel products), and conclude and sign a contract with the suppliers. Another way is for the users to wait until their construction and production plans are finalized before ordering their supplies according to their needs (such as in the case of non-ferrous metals).

Supply by coupon. Issue "supply coupons" according to allotted quotas, so that the users may use them to get their supplies from the supply centers or units as the occasion demands according to the types meeting their needs, without being subject to restrictions on time, place of supply, kinds of materials, or specifications. Coupons may also be used to transact processing orders (such as for copper, aluminum, lead, zinc, copper products, aluminum products, lead products, cast iron, etc.)

Supply by verifying need. Supply the users with goods and materials according to their actual needs, with or without assigned quota. Some of the users are supplied according to their scheduled consumption, others according to their processing speed, still others according to their coupons kept in hand, and still others according to the fluctuation of their inventory (such as in the case of steel products, hard alloys, chemical industry products, timber, construction materials and motor-driven and electric equipment of the second category, used for production, maintenance, capital construction, technical renovation or scientific research).

Wide open supply. Supply the users without restrictions of any kind, at all times or during assigned periods, according to the availability of goods and materials and the actual situation of the users concerned. Such unrestricted supply may be limited to spare parts and fractional needs (such as most of the products of the machinery and electrical equipment industries of the second category, some of the products of the electrical equipment industry coming under unified distribution, products of the chemical industry, and metal materials).

Open more retail centers to meet civil needs, allowing the buyers to buy small portions of products (such as in the case of chemical industry products and steel materials).

Develop the equipment rental business (such as all kinds of machines, equipment, hand tools and tools used in building construction).

All these measures have simplified matters to the convenience of the users, while guaranteeing the satisfaction of needs, reducing social inventory, and speeding up the circulation of goods and funds.

[Article by Wu Zhong [0124 0022]]

Establish Capital Goods Marketplaces

Since 1979, there has been a growth of market regulation of the circulation of producers' goods in line with the principle of regulating the economy both by planning and by the market. Sizable producers' goods marketplaces have taken shape in Shanghai, Jiangsu and Sichuan and other localities after trade fairs were held. In these marketplaces, transactions can be conducted in many ways (such as at assigned booths, through salesmen, by mail or telegraphic orders, or by holding large trade fairs), the sellers and buyers enjoy total freedom (without being restricted by the categories of goods and materials, by the demarcations of administrative areas, by the chain of command of enterprises, and by the two types of socialist ownership concerned), and the prices are flexible (such as according to state-assigned prices, local prices or floating prices). In these marketplaces, the traditional view that capital goods are not commodities and cannot be traded on the market was overthrown, enabling the buyers to get supplementary supplies when plan allocations are insufficient and allowing redress imbalances of supplies among localities and enterprises. It is also beneficial to a rational development of competition, and to encouraging enterprises to improve the quality and increase the variety of their products and to lower their costs. These marketplaces have received the enthusiastic support of the producers as well as the consumers.

The capital goods service companies of the materials supply departments of the various localities are the main organizers of capital goods marketplaces. At present, there are some 500 capital goods service companies in the whole country. Their "four agents and one adjustment" business (whereby they serve as purchasing agents, marketing agents, shipping agents, and processing agents as well as helping in trading activities) has seen a further growth, so that they have formed the beginning of a nationwide capital goods service network. Their annual business volume amounts to 3 billion yuan, of which one billion came from the transactions conducted in the 50-odd marketplaces scattered in the various localities.

The materials supply departments of Shanghai, Beijing, Tianjin, Sichuan and Liaoning are making preparations for establishing permanent capital goods marketplaces to serve as regional centers for trade, market information and services, to create the conditions for organizing according to plan and further invigorating market regulation of producers' goods.

Make Use of Overstocked Supplies

Taking inventory of warehouse stocks is an important job in speeding up the turnover circulation of commodities and making fuller use of goods and materials. Taking inventory involves three tasks: counting the materials in stock; determining the stock turnover quota; and making use of overstocked supplies. In 1979, the various localities and departments stressed carrying out the latter two tasks, after the first was out of the way.

By the end of 1979, most of the enterprises in China had completed determining their stock turnover quotas. This paved the way for improving their management and administration. According to statistics compiled at the end of 1979 by 27 provinces, municipalities and autonomous regions and 34 departments of the central government, the overstocked goods and materials identified by this inventory of their enterprises amounted to 31 percent of the total value of goods in storage in these units, including 20.5 percent of the total amount of steel materials in storage and 34 percent of the total value of machinery and electrical products in storage.

The various localities and departments paid attention to the work of closely coordinating the utilization of their overstocked supplies with the campaign for increasing production and practicing economy. They have adopted positive measures to make use of overstocked supplies and speed up their enterprise capital turnover, such as having such supplies transferred, sold by agents or at trade fairs, reprocessed and fixed for marketing, or otherwise utilized before ordering more supplies, and asking the banks to control their loans accordingly. Statistics show that of the total value of overstocked materials, 34.4 percent were utilized in 1979, including 63 percent of the overstocked steel materials and 30.6 percent of the overstocked machinery and electrical products.

Launch a Fuel Conservation Emulation Drive

To assure fuel supply and minimize waste, the State Council in 1978 decided to ration the supply of coal and oil "in the same manner as grain," and approved the "Unified Fuel Control and Rationing System" formulated by the State Planning Commission in coordination with other departments concerned. This system has been put into practice throughout the country. Since March 1979, the fuel companies of 72 cities in 18 provinces, municipalities and autonomous regions have carried out an emulation drive with marked success in improving fuel control and conservation.

In the past year, of the 25,900 major coal-consuming enterprises at the world level and above in these cities, 24,300 (93.8 percent) put into operation rationing by coupon; 11,400 (44 percent) assigned coal consumption quotas to their workshops, shifts of workers, and furnaces; and 19,600 (75.7 percent) adopted monthly and quarterly coal consumption checking systems. By the end of 1979, 12,200 enterprises (47.1 percent) reduced their coal consumption to their lowest historic levels.

In 1979, China conserved 23 million tons of coal and 2 million tons of fuel oil. In the 72 cities which participated in the fuel conservation emulation drive, their industrial production values increased by an average of 9.87 percent, while the increase in fuel consumption amounted only to 0.53 percent. In 32 cities, including Shanghai, Nanjing, Wuhan and Dandong, in particular, their industrial production value increased by 9.16 billion yuan, or 10 percent, while their fuel consumption was reduced by 1.286 million tons, or 4.6 percent, thereby fulfilling their goal of increasing production through fuel conservation and speeding up industrial development through minimizing fuel consumption.

[Article by Wu Zhong]

Popularize the Multiple-Purpose Utilization of Timber

In China, the direct timber utilization rate amounts to about 50 percent. What is left over after timber processing is mostly disposed of as waste. In Hangzhou Municipality of Zhejiang Province, however, an integrated complex to process and supply timber was established to reform the timber management system. It adopted the multiple-purpose utilization of timber from centralized processing to centralized supply of timber and finished and semifinished timber products to capital construction and packaging units throughout the city, run by Hangzhou Municipality, Zhejiang Province, and the central government, thereby increasing the timber utilization rate to 95 percent (72.7 percent for the direct utilization of the original timber and 22.3 percent for the utilization of leftover bits and pieces and damaged lumber).

In China, the forested area is relatively small, covering only 12.7 percent of the territory, averaging less than 10 cubic meters of timber per capita, much less than the world average. With uncontrolled lumbering in excess of regrowth in forests over many years past, the timber resources in China have so diminished as to adversely affect the production, construction and livelihood of the people. For this reason, it is important to popularize the experience of Hangzhou to solve the shortage in timber supply by centralizing timber processing work and raising the timber utilization rate. In September 1979, the State Council promulgated the "Report of the State Planning Commission, the State Economic Commission, and the State Supplies Bureau on Popularizing the Experience of the Hangzhou Timber Company to Increasing the Rate of Utilization of Timber," stipulating that all cities in China assign only their timber companies to engage in the integrated and organized processing and supply of timber, and that with the exception of absolute needs requiring the use of raw timber (such as for tunnel supports, piles, powerline poles, etc.), no unprocessed timber should be allocated directly to users anymore. In November 1979, a National Timber Work Conference was held, at which it was decided that in 1980 timber processing and supply be integrated on a trial basis in 45 cities including Beijing, Tianjin and Shanghai, and that this practice be followed by all cities in 1981. It was also suggested at the conference that the timber processing capacity in cities be completely readjusted within 2 to 3 years, that timber products be standardized as soon as possible, that timber be utilized comprehensively to serve many purposes, that the production of plywood be promoted, that in 3 to 5 years all the leftovers in timber processing in the cities be utilized, that the direct timber utilization rate be raised to over 70 percent, and that the multiple-purpose timber utilization rate be raised to over 90 percent.

[Article by Wu Zhong]

Reform of Management and Supply of Tires

China is short of rubber. More than one-half of its rubber supply is imported. At present, over one-third of total rubber consumption in China is used in the manufacture of tires. For this reason, to conserve rubber, it is necessary to reduce tire consumption. Since 1974, Jinzhou City in Liaoning Province has been employing the system of supplying tires to industrial and agricultural units only after checking their actual needs and requiring the exchange of an old, worn tire for each new one, instead of the old method of application for new tires through administrative channels. In addition, the city made great efforts to organize the business of retreading old tires. Thanks to these measures, the city succeeded in reducing the number of new tires supplied per year per motor vehicle by 65 percent, for a total savings of more than 6,800 sets of tires in 6 years under the quotas allotted by the state.

To popularize this successful experience of Jinzhou, the State Planning Commission and the State Economic Commission in 1978 issued the "Trial Measures Governing the Unified National Tire Supply and Retreading Business" to be carried out by the State Supplies Bureau. By the end of 1979, the various localities completed taking their motor vehicle inventory and provided a tire file for each vehicle. Two-thirds of the 2,500 tire supply units in the country put into practice the system of supplying tires only according to actual needs. Thanks to the adoption of this system, the volume of new tires supplied has fallen in all localities, as much as 30 percent or more in some of the provinces, municipalities and autonomous regions. At present, the supply of tires in China is sufficient in the main to meet the needs, with the exception of certain particular specifications. This marks a radical change from the shortage of tires in China in the past many years.

In view of the good results achieved by the various localities in supplying new tires and renewing old tires only according to actual needs, the State Supplies Bureau decided that, beginning in 1980, a system be put into practice on a trial basis in Beijing, Tianjin, Shanghai, Sichuan, Hunan and Liaoning for the enterprises directly controlled and supplied by the 24 ministries of the Central People's Government to give up their tire allocation quotas and to get their tire supplies from the supplies units nearby according to actual needs.

[Article by Wu Zhong]

Material Conservation and Reclamation

In the course of readjusting the national economy and reforming enterprise management, the various economic departments, enterprises and broad masses of the people began to pay great attention to the conservation, use of substitutes for and reclamation of materials, particularly in the case of fuels, power, and raw materials. In 1979, the major industries reduced their consumption per unit product. According to statistics compiled by the metallurgical, coal, electric power, petroleum, chemical, railway, communications, light, textile, and construction material industries, for the 64 major products of 470 key enterprises, the average consumption of fuels and major raw materials per unit product per year dropped for 45 of them, or 20.3 percent, in 1979 as compared to 1978, while it rose for 19 of them, or 29.7 percent. Thanks to the reduction of consumption by a large number of products, these industries in the year 1979 saved 6.3 million tons of coal (including coke converted to coal equivalent at a given ratio), 782,000 tons of industrial oil, 326,000 cubic meters of timber, 73,000 tons of acid and alkali, and 590,000 tons of iron and steel material. The principal measures adopted to reduce consumption included the enforcement of consumption quotas, the promotion of "Energy Conservation Month," the adoption of new technology and new processing methods, and the issuance of conservation bonuses.

Great progress was achieved in conserving and using substitutes for timber. According to incomplete statistics compiled in 28 provinces, municipalities and autonomous regions, more than 1.76 million cubic meters of timber were saved in 1979 through the adoption of fiberboard, steel materials, light burned magnesia, calcerous plastic, tree branches, and other materials as substitutes for timber, the reclamation of old timber for reuse, the rental of the means of construction, and efforts to increase the yield of useful lumber from logs.

The reclamation of metals reached a historical high level in 1979. The annual ferrous scrap metal reclamation plan was overfulfilled by 6.7 percent, and the quota of reclaimed ferrous scrap metal handed over to the state by 28.7 percent, topping historical records. The proportion of reclaimed steel waste of better quality increased from 47 percent in 1978 to 56 percent, thereby enabling steel plants to use more scrap steel as a raw material.

[Article by Hu Runsong [5170 3387 2646]]

Producers' Goods Service Network Established in East China Region

In 1979, the producers' goods service companies in the six provinces and one municipality in East China adopted some new measures in their work to invigorate the supply of materials and promote production. Large quantities of overstocked and overproduced products were sold or otherwise disposed of during 1979 as a result. In Shanghai alone, these companies sold more than 170 million yuan's worth of such goods and materials for Shanghai and the other provinces, and procured and processed many urgently-needed supplies for more than 8,000 industrial and mining enterprises. During 1979, Shanghai arranged for the processing of 290,000 tons of pig iron into steel materials for the East China Region. In August 1979, the first East China Region Coordination Conference was held in Shanghai at which the participants from many areas proposed that after fulfilling state plans they be allowed to exchange grain, edible oils and fats, and other agricultural and subsidiary products for chemical fertilizer, steel materials, coal and other raw materials, through the coordinated market.

In view of the new changes in producers' goods servicing, leaders of more than 80 producers' goods service companies in Shanghai and the six provinces of East China held a meeting in Shanghai in early 1980, at which it was formally decided to establish the East China Region producers' goods service network to speed up circulation of goods, assure the satisfaction of urgent needs in production, and improve producers' goods service work.

MINERAL RESOURCE, TEXTILE, POWER, MACHINERY, LIGHT INDUSTRIES DESCRIBED

Beijing and Shanghai ZHONGGUO BAIKE NIANJIAN 1980 [YEARBOOK OF THE GREAT ENCYCLOPEDIA OF CHINA, 1980] in Chinese Aug 80 pp 313-335

[Text] Industry

[Article by Hong Huiru [3163 1920 1172]]

General Description

After 30 years' construction, China has built up a fairly complete industrial system with different departments and a certain technological level. The old trades have been greatly developed, while many new ones, such as the petrochemical industry, the electronic industry, the atomic energy industry and the aerospace industry, have been, or are being established. China is now able to design and produce many types of products requiring fairly complex technology to meet the requirements of economic construction and people's livelihood.

China's raw material industry is now on a fairly firm foundation. In 1979, its output of coal, crude oil, electric power, cement, steel, sulphuric acid, soda ash and chemical fertilizers, ranked among the top 10 in the world. Along with the petrochemical industry, the industries of chemical fiber, synthetic rubber, plastics and other new materials have also rapidly developed. The output of chemical fibers now ranks seventh in the world. China is also able to produce many types of metal and nonmetal materials to meet the requirements of national defense and sophisticated technology. In certain technical fields, such as the techniques of coal-dust blowing in blast furnaces, the reduction of gangue consumption in aluminum refining, and in the separation of associated metallic ores, China is unique in the world.

Instead of mainly engaging in repairs and assembling, China's machinery industry departments have become machinery manufacturing departments with a fairly high level of technology. In addition to automobiles, tractors, airplanes, 10,000-ton ships, and 5 million operations per second electronic computers, it has now developed its technology from that of purely copying from others to that of designing its own products; and from the manufacturing of single engines to the production of complete sets of equipment. It has already designed and manufactured 2,500 cubic-meter blast furnaces, rolling machines for 4,200 millimeter thick steel plates, equipment for 300,000-ton synthetic ammonia production, 300,000 kilowatt thermopower generating assemblies, and other complete sets of equipment.

The scopes of its light and textile industries are much enlarged. The sources of raw materials for these industries are increased, along with the increase of designs and varieties and the improvement of quality. In the textile industry, since the production of knitwears of mixed natural and chemical fibers began in 1961, the quantity of chemical fibers used has increased to 15 percent of the total quantity of all fibers used. Among the cotton textile products, the proportion of comfortable and economical cotton knitwears has increased from 9 percent to 18 percent in 1979; and that of worsted materials in wool fabircs increased from 50 percent in 1949 to 67 percent in 1979. Since liberation, the light industry departments have gradually produced sewing machines, cameras, wrist watches, transistor radios, TV sets, synthetic detergents, movie films, washing machines, refrigerators, tape recorders and various types of plastic products which have greatly enriched people's life.

The speed of China's industrial developments is fast even by the world standard. In 1979, the total national industrial output (computed on the basis of invariable prices in 1970) amounted to 459.1 billion yuan, being 42.5 times that of 1949 with an average annual increase of 13.4 percent. In the same period, light industry increased 21.8 times with an average annual increase of 11 percent; heavy industry increased 97.6 times, with an average annual increase of 16.6 percent. In 1979, coal output reached 635 million tons, being 19.8 times that of 1949, with an average annual increase of 10.5 percent; the output of crude oil amounted to 106 million tons, being 884.6 times that of 1949, with an average annual increase of 25.4 percent; generated power amounted to 281.95 billion kwh, an increase of 64.5 times that of 1949 with an average annual increase of 15 percent; steel output was 34.48 million tons, being 218.2 times that of 1949, with an average annual increase of 19.7 percent; chemical fertilizer output was 10,654,000 tons, being 1,775.7 times that of 1949, with an average annual increase of 28.3 percent; the output of cotton cloth was 12.15 billion meters, being 6.4 times that of 1949, with an average annual increase of 6.4 percent; the output of machine-made paper and paper board was 4.93 million tons, being 44.8 times that of 1949 with an average annual increase of 13.5 percent.

After 30 years' construction, China's industry now consists of 350,000 enterprises, while a fairly strong contingent of technicians and skilled workers has been formed. In 1979, the number of industrial workers in units owned by the whole people reached 31.09 million, an increase of 5.1 times over that of 1952. In the same period, the labor productivity of the total industrial labor force increased 1.8 times, while the average wage of industrial workers and staff members increased 0.5 times. The proportion of the total industrial output value in the combined industrial and agricultural output has risen from 30 percent in 1949 to 74 percent. The industrial level, compared with that of old China, is now vastly different. It has become an important material base for the accomplishment of the four modernizations.

After 30 years' construction, the geographical distribution of productive forces has much changed. The resources in the hinterland are being exploited and utilized, and a number of new industrial towns have appeared in various provinces (regions) of the hinterland.

Our industrial achievement has been tremendous. Yet, we have wasted some time because of the two setbacks we experienced during the early part of the second five-year plan and the Great Cultural Revolution. However, we have learned our lessons from these experiences. The wrong methods used in the past 20 years led to certain irregularities in the industrial economic structure and the system of industrial management. For example, the relationship between agriculture, light industry and heavy industry is not proportionate, and our management efficiency and technical level are far behind those of the advanced countries. In·the Third Plenum of the 11th Party Central Committee held in 1978, the policy of "readjustment, restructuring, consolidation and improvement" was introduced. Then in June 1979, under the leadership of the Finance and Economic Commission of the State Council, economic theorists and practical workers were organized to conduct investigations and study to further clarify the situation in order that the readjustment and restructuring could be guided by more specific goals. The present irrational economic structure will then be replaced by a rational one, and the present system of industrial management, characterized by excessive administrative control and low efficiency will be replaced by an efficient system of administration according to economic laws. China's industry will then be equal to the responsibility of a leading role in the national economy in accomplishing the four modernizations.

Industrial Reorganization under the Principle of Specialization and Coordination

To suit industrial development in China during the 1960's some industrial departments formed more than 10 national and local specialized companies (or general plants) on an experimental basis and gained certain success. When the "gang of four" were on the rampage, these experiments were criticized as being "capitalist," and the specialized companies (or general plants) were abolished.

After the smashing of the "gang of four" and along with the national economic recovery and industrial development, some departments, then under diversified leadership and decentralized management, became increasingly incompatible with socialized mass production, and the localities and enterprises raised the question of organizing specialization and coordination in production from different points of view according to their own conditions. In his summing-up report delivered before the Third National Agricultural Mechanization Conference on 26 January, Vice Premier Yu Qiuli [0151 4428 6849] proposed that the farm machinery industry should be reorganized in various provinces throughout the country according to the principle of specialization and coordination. The First Ministry of Machine Building then held a special conference in Lanzhou for this purpose.

In July 1978, the Party Central Committee relayed to the lower levels the "Decisions of the CCP Central Committee on Some Questions Concerning the Acceleration of Agricultural Development (Draft) (called the "30-Point Decision on Industry" for short), further clarifying the need to reorganize industry according to the principle of specialization and coordination in order to accelerate industrial development. Later, some regions in Jiangsu and Sichuan and some industrial departments actively carried out industrial reorganization according to this principle, and did a great deal of work in this direction.

In the summer of 1978, the State Economic Commission, in consultation with Beijing, Shanghai and Tianjin Municipalities and Liaoning Province first set up experimental points for the sake of accumulating experiences. By the summer of 1979, action was taken mainly along the following lines:

First, investigation on the local situation of industrial development and the existing problems so as to ascertain the orientation of industrial reorganization; second, readjust the relations of affiliation among some enterprises so that each trade or undertaking will be under the unified leadership of its own department in charge; third, establishing a number of specialization companies (or general plants); fourth, further planning and reorganization inside the companies (or general plants); and fifth, the trial operation of a small number of companies (or general plants) in the manner of enterprises.

For more than 1 year, these six provinces and municipalities have reorganized or formed their specialization companies according to the principle of specialization and coordination with certain success.

(1) The situation of diversified leadership and decentralized administration has begun to change and a large number of scattered enterprises have been organized to ptomote production under unified management and direction. For example, after the reorganization of the eight production factories originally affiliated to six districts, counties and bureaus in the sewing machine trade, their output in the first half of 1979 exceeded that of the same period in 1978, or before the reorganization, by 57 percent.

(2) Unified planning and rational division of work have initially changed the orientation of production for some plants, developed the production of key items and goods in short supply for the market, and improved the quality of products. The volume of export trade has also increased.

(3) Specialized production was organized according to the special characters of products, spare parts and accessories and work process, and the potentials of enterprises were tapped to improve the economic results and to promote the enterprises' technical transformation.

(4) Enterprise management was strengthened and some backbone technicians were trained.

In coordination with industrial reorganization, the problems of prevention and treatment of the "three wastes" and the practice of economy among some plants have been solved.

Furthermore, in recent years, some provinces, municipalities and autonomous regions including Beijing, Shanghai, Tianjin, Jiangsu, Shandong, Gansu, Yunnan, Guangxi and Shanxi have carried out investigations followed by experimental reforms in the rational organization and dispatching of vehicles in transportation. These experiments have been a success.

Main Industrial Outputs of China

产品 Items	单位 Unit	1949 年 Year	1952 年 Year	-1978 年 Year	1979 年

25. Wrist watches in 10,000 pieces

Five Documents Issued by the State Council on Restructuring the Management of State-Operated Enterprises

In the Communique of the Third Plenum of the 11th CCP Central Committee, it was pointed out that "one of the serious shortcomings in the structure of economic management in our country is the overconcentration of authority, and it is necessary boldly to shift it under the guidance from the leadership to lower levels so that the local authorities and industrial and agricultural enterprises will have greater power of decision in management under the guidance of unified planning... These measures will bring into play the initiative, enthusiasm and creativeness of four levels, the central departments, the local authorities, the enterprises and the workers, and invigorate all branches and links of the socialist economy." Accordingly, the State Council issued the following five documents on 13 July 1979:

1. "Certain Regulations Concerning the Expansion of the Decision-Making Power in Business Management by State-Run Industrial Enterprises": Under these regulations, the enterprises has the power to formulate and carry out supplementary plans, provided the fulfillment of state plans is guaranteed, and the state will gradually enforce the system of profit-sharing with the enterprises. The depreciation rate of fixed assets will be gradually raised and the system of payment for the use of fixed assets and the granting of full credit for circulating capital will be adopted. The enterprises will be encouraged to develop new products and to increase their export trade. They will choose their own workers and staff members in accordance with the state's labor planning, and measures will be taken to reduce their extraneous burdens. At the same time, the task which the enterprises must fulfill should be clearly spelled out so that the enterprises can effectively exercise their decision-making power in dealing with manpower, money, materials, supply, production and marketing. Their work should be guided and regulated by the state's unified planning, unified policy and unified disciplines.

2. "Regulations Concerning the Practice of Profit-Sharing by State-run Enterprises": According to these regulations, all enterprises practicing independent business accounting and making profits can retain a certain percentage of these profits to be used for building up funds for the development of production and for the workers' welfare and rewards so as to strengthen the enterprise's economic responsibility and to combine the interest of the state, the enterprise, and the individuals. This will help arouse the enthusiasm of the enterprises and their workers and staff members in doing a good job of economic accounting and in tapping the potentials for increasing production and in practicing economy in order to accumulate more funds for the state.

3. "Provisional Regulations Concerning the Levy of Fixed Assets Tax from State-run Industrial Enterprises": It has been decided that the system of free use of fixed assets has to be changed and the enterprises can no longer be free from economic responsibility in the use of state assets. Holding industrial and communications enterprises responsible for the fixed assets will encourage them to improve their management and business results.

4. "Provisional Regulations Concerning Raising the Depreciation Rate of the Fixed Assets of Industrial Enterprises and Improving the Methods of Using Depreciation Funds": Starting from 1980, the depreciation rate of fixed assets for industrial and communications enterprises will be gradually raised on the basis of increasing profits, in order to help the old enterprises tap their potentials and renovate and

transform their equipment and to give full play to the role of the existing enterprises in accelerating the national economic development.

5. "Provisional Regulations on the Trial Granting of Full Credit for Circulating Capital": To change the present phenomenon of diversified control of the circulating capital and the present situation where the size of the circulating funds used by an enterprise is not related to the economic benefits of the workers and staff members of the enterprise, the People's Banks will grant full credit to the enterprises for circulating funds. This will help strengthen the system of inspection and supervision by the bank over the enterprises' business activities and further encourage the enterprises and their workers and staff members in the effective control of their circulating funds.

Many provinces, municipalities and autonomous regions have already begun their experiments according to the regulations contained in these five documents.

Experiments in the Expansion of Decision-Making Power for the Enterprises

At the First Session of the Fifth National People's Congress, Premier Hua Guofeng pointed out in his "Report on the Work of the Government": "We have to conscientiously sum up our experiences and gradually reform and perfect the system of enterprise management." In the past several years, many localities have adopted measures to readjust and restructure the original system of management and to expand the decisionmaking power of enterprises. In October 1978, Sichuan Province first selected the Chongqing Iron and Steel Company, the Ninjiang Machine Tool Plant, the Sichuan Chemicals Plant and the Xindu County Nitrogenous Fertilizer Plant, and two other enterprises for the experiment, and gained some success. By the beginning of 1979, the experimentation had developed to include 100 enterprises affiliated to the Ministries, the province, municipalities, prefectures and counties. The province also formulated tentative measures embodied in 14 Articles concerning, among others, the tryout of profit sharing, raising the ratio of the enterprise's share of funds allowed for the depreciation of fixed assets, granting full credit for circulating capital, improving the regular bonus system, sharing foreign exchange, strengthening the power of the enterprises in offering rewards and meting out punishment and in the appointment and removal of personnel as they think fit. Thus the power of the experimental enterprises was further expanded. Similar experiments were carried out among some enterprises in other provinces, including Yunnan and Anhui.

To step up the experimentation, the State Council issued five documents in July 1979, concerning the expansion of decision-making power for the enterprises, and calling on the relevant departments in the provinces, municipalities, regions and the central authorities to select a small number of enterprises for the experiment. These experimental enterprises must have been consolidated under strong leading bodies and have fairly regular production procedures and management. The State Economic Commission also selected eight enterprises in Beijing, Shanghai and Tianjin for the experiment.

By the end of 1979, there were nearly 2,000 industrial and communications enterprises in 21 provinces, municipalities and autonomous regions undergoing the experimentation of expanded decision-making power and the profit-sharing system. These experimental enterprises amounted to 7 percent of the total number of industrial enterprises included in the state budget, and their industrial output value amounted to 30 percent of the combined total of these industrial enterprises.

Remarkable economic achievements have been won in the experiments on the decision-making power of the enterprises. First, it has promoted production by not only increasing the total output value but also raising the quality of products. The system of profit-sharing has resulted in benefits for the state, the enterprises, and the workers and staff members. Furthermore, since the conditions are favorable for technical transformation through self-reliance, it arouses the enthusiasm of the enterprises in tapping potentials and renovating and transforming their equipment, and in expanding their productive capacity. Because of their heavier responsibility, the enterprises have attached greater importance to their management and economic accounting.

To make the experimentation an even greater success and to sum up the experiences, the State Economic Commission issued a notice by the end of 1979 to the effect that the experiment would not be further expanded in 1980, and that starting from 1980, the share of profits for the enterprises should be calculated according to the excess over a certain basic amount of profit instead of being based on the total profit.

State Economic Commission Held Research Classes on Enterprise Management

To meet the requirements of socialist modernization, the State Economic Commission under the State Council has since March 1979 held research classes on enterprise management for the cadres. Among the students of these classes were directors and vice directors of the economic committees of various provinces, municipalities and autonomous regions as well as the main industrial cities; the directors of various departments and bureaus in charge of the enterprises in the industrial and communications sectors, and the directors of large and medium-size plants. Beginning from the fourth term of the research classes, the chairmen and vice chairmen of trade unions in various provinces, municipalities and autonomous regions also participated. Therefore, the name of these classes was changed to "Research Class on Enterprise Management of the State Economic Commission and the All-China Federation of Trade Union."

The course of these research classes included these four different aspects:

1. The ideological line, mainly related to study of the question of practice as the sole criterion for the testing of truth, and of the relevant speeches by the leaders of the central authorities;

2. Economic theories, mainly the theory of socialist commodity production, such as giving play to the mechanism of the market and the coordination of the regulative roles of planning and the market with great importance attached to the former;

3. Enterprise management mainly consisting of its general scope, planned management, quality control and economic accounting; and

4. Industrial management, mainly consisting of its general scope, the industrial structure, the distribution of productive forces and the energy resources.

In the research classes, the students have to mainly rely on self-study, while in dealing with important questions, well-known experts and scholars at home or abroad are invited to give lectures. Regular group discussions, inspection visits to plants are also organized to deepen the students' understanding of these problems and to improve the result of their study.

Each term lasts approximately 2 months, and by the end of 1979, four terms had been held, and some 470 persons trained.

The provinces, municipalities, autonomous regions and the various industrial and communications departments also attached great importance to the training of the cadres who are on active duty. According to incomplete statistics compiled by 29 provinces, municipalities and autonomous regions and 18 departments and general bureaus of the industrial and communications sector, more than 460,000 persons, including some 153,000 leading cadres at or above the county levels, participated in various types of economic management training classes in 1979. The Jiangsu Provincial Economic Committee has already sent more than 12,000 economic management cadres at or above the county level for rotational training. In Shaanxi, 30 percent of the cadres at the same levels attended the economic management training classes.

All-Out Activities of China Enterprise Management Association

The China Enterprise Management Association was established in Beijing on 3 March 1979, with one each president and adviser and nine vice-presidents. The president was Yuan Baohua [5913 1405 5478], Vice Minister of the State Economic Commission, while Deng Liqun, [6772 0500 5028], Vice President of Chinese Academy of Social Sciences, served as adviser. The highest organs are the Council and the Standing Council. There are 61 council members, including 41 standing council members. The secretariat is responsible for the day to day operation of the association, and the secretary general was Zhang Yanning, [1728 1750 1380], director of the Comprehensive Bureau. The China Enterprise Management Association consists of 63 member groups which are mainly branch associations, large back-bone enterprises, the finance and economic professional units and economic research units of universities and vocational colleges; 132 individual members, including 51 professors, research workers, accountants and engineers from all 29 provinces, municipalities and autonomous regions. Branches of this association have already been opened in Beijing, Tianjin, Shanghai, Liaoning and Lanzhou. These five branch associations have a total of some 230 council members, more than 500 group members and 1,000 individual members.

The function of the China Enterprise Management Association is to improve enterprise management through the activities of this association in order to serve China's four modernizations. The specific goals of the association are as follows:

1. To translate and publish books and periodicals and to supply information on the situation of enterprise management at home and abroad. The Enterprise Management Publishing House, affiliated with the China Enterprise Management Association, will compile and translate books and periodicals in a planned way to supply information on the experiences, methods and means used in enterprise management at home and abroad, and to actively promote the improvement of business management of enterprises.

2. To train managerial cadres. Besides holding unscheduled report meetings and academic exchange meetings and inviting Chinese and foreign scholars to give academic talks, the association will also help the departments concerned run

research classes for the leading cadres at various levels. These activities will help raise the professional knowledge and technology of the managerial cadres and the management level of Chinese enterprises.

3. To sum up the experiences of enterprise management and to participate in the experimentation of management restructuring. The association will organize its council members and members as required to conduct in-depth investigations and study of the enterprises, to help the enterprises sum up their experiences, and then provide active guidance in the experiment on their management restructuring.

4. To conduct international exchange activities. The China Enterprise Management Association will do everything possible to establish contacts with the enterprise management organizations and groups in the world, and through the exchange of visits, inspections, advanced study, supply of data and other programs for the exchange of experiences in enterprise management, strive to apply and popularize certain methods of scientific management which have proved to be effective.

The China Enterprise Management Association made all-out efforts in promoting these activities in 1979.

Democratic Election of Workshop Cadres

Speaking before the Ninth National Trade Union Congress in October 1978, Vice Premier Deng Xiaoping said: "Workshop directors, section chief and group heads in every enterprise must in future be elected by the workers in the unit." This is an important measure for the broad masses of workers to exercise their power as masters of the enterprises under the socialist system of public ownership.

To gain experiences in the democratic election of workshop directors, experiments have been carried out since 1978 among the enterprises in some provinces and municipalities. There are 48 enterprises in the system of the Beijing Municipal Building Material Bureau, with a total of more than 230 workshops. Leading cadres for these workshops have all been appointed through democratic elections.

The democratic elections of workshop cadres in the experimental enterprises were carried out under party leadership, and the various organizational jobs were undertaken by the political organizations of the party committee in collaboration with the plants' trade unions. The role of the trade unions was thus given full play.

The methods and procedures of democratic election of workshop cadres are as follows:

1. Go deep among the workers to ascertain the ideology of the cadres and workers;

2. Carry out effective ideological work and bear in mind the existing problems so as to familiarize the cadres and workers with the significance, purpose and specific methods of democratic election.

3. Organize the workshop directors to report on their work before the workers and staff members of the units. While affirming the achievements, they should also reveal the shortcomings and carry out sincere self-criticism for their own defects and mistakes. Then the masses should be mobilized to evaluate the cadres with the method of "dividing one into two." These activities will give the masses an

opportunity to understand the cadres thoroughly, to criticize them, and at the same time help those who have erred to mend their way and to win the workers' understanding.

4. Explain to the workers and staff members about the conditions and responsibility required of the candidates for workshop cadres and let the masses nominate the candidates with no strings attached by the plant leadership.

5. Carry out election with secret ballot and with more candidates put up than the cadres to be elected.

6. Conduct ideological work on the successful as well as the unsuccessful candidates. The successful ones should be reminded that they should live up to the workers' trust and expectation by doing their work well, while the unsuccessful ones should take a proper attitude toward their defeat through an orderly transfer of their duties and then take up their new jobs cheerfully.

As proved by the experiments, the fear that democratic election of workshop cadres would create chaos and adversely affect production following a complete reshuffle of cadres is groundless. According to investigations on the experiments carried out in Beijing, Shandong, Heilongjiang, Ningxia and 11 other provinces, municipalities and autonomous regions, 87.4 percent of the cadres were reelected, and the change only affected 12.6 percent of them and most of the unsuccessful candidates were old and weak, lacking organizing ability, or seriously divorced from the masses.

In the units of all localities where democratic election of workshop cadres by the workers has been carried out, the enthusiasm of the workers in participating in the management of the enterprises is further aroused, and the elected cadres' mass concept and vocational devotion are further strengthened. Thus the relationship between the workers and the cadres has become closer while the management and production of the enterprises, where such elections have taken place, have all improved in varying degrees.

[Article by Liu Yuanzhang [0491 3293 1728]]

Quality Control Strengthened

Great importance has been attached to quality control since the downfall of the "gang of four." In April 1977, the State Council held a national conference to learn from Daqing and called on enterprises throughout the country to fight a mass battle of quality control. In a meeting held by the First Ministry of Machine Building in September of the same year for exchanging experiences in raising production quality and consolidating enterprise management, a proposal was made to start a "trustworthy product quality" campaign. In August 1978, the First Ministry of Machine Building enforced the "Three Guarantees" (meaning the guarantee of repair, replacement and return) beginning with farm machinery. In July 1978, the "30-Point Decision on Industry" was publicized and Point 19 stressed the need to pay great attention to quality, varieties and specifications. The national conferences to learn from Daqing held in the months of May, June and August 1978 by the textile industry, the light industry and the machinery industry, all called for the consolidation of enterprises and the raising of product quality. In 1979, the work of quality control continued to make headway.

The Launching of the "Quality Month"

In July 1978, the State Economic Commission decided that September be designated as "Quality Month" every year. In the first "Quality Month" meeting broadcast by the radio and the TV network in September 1978, Vice Premier Kang Shi'en of the State Council mentioned the specific requirements of the "Quality Month" in his speech as follows: 1. Deepen the criticism of the crimes committed by the "gang of four" in causing the deterioration of quality; 2. Stress the harms which poor quality would bring; and 3. Make a real effort to set up rules and regulations for the basic work of quality control.

In April 1979, the State Economic Commission issued a notice on the plans for launching the second "Quality Month." In August of the same year, the First National Representative Conference of Quality Control Groups was held. The representatives reviewed their achievements in quality control during the previous year and pointed out that since the launching of the "Quality Month" campaign in 1978, mass quality control on the industrial and communications front of China had made great progress, and quality control groups had appeared in large numbers. In the machinery industry departments alone, more than 5,100 teams and groups were named "trustworthy product quality" units. Thanks to strengthened quality control, the quality of products among various trades and undertakings has steadily risen. In the second National "Quality Month" Conference held in the People's Great Hall of the Capital, and broadcast and televised in September of the same year, Vice Premier Kang Shi'en said that after this "Quality Month," all industrial products should within the following year be able to conform to the State's quality standard, restore all the brand-name products, and catch up with or surpass the advanced levels at home and abroad. In accordance with the "Regulations of the People's Republic of China for Awarding Fine-Quality Prizes" issued by the State Economic Commission with the approval of the State Council in June 1979, the Conference awarded 51 gold medals and 121 silver medals for fine-quality products. These were the first national awards ever given for fine-quality products.

Experiment of All-Round Quality Control

In May 1977, the experiment of quality control in the Qinghe Woolen Textile Mill of Beijing and the Beijing General Internal Combustion Engine Plant was a success. Then in May 1978, a group of the First Ministry of Machine Building of China went to Japan for inspection on invitation by the Komatsu Manufacturing Center of Japan. Later, representatives of the Komatsu Manufacturing Center visited the Beijing General Internal Combustion Engine Plant for an exchange of technology in quality control. In July of the same year, the First Ministry of Machine Building held the first term of study classes on all-round quality control. This was followed by similar study classes and experiments in various localities and departments throughout the country.

In 1979, the number of experimental units in all-round quality control was increased. During the "Quality Month," the People's Central Broadcasting Station carried a series of talks on all-round quality control. By the end of 1979, more than 1 million people had participated in this type of study class, and, except for Xizang, all provinces, municipalities and autonomous regions had their experimental enterprises which numbered more than 870. In August of the same year, a China Quality Control Association was formed in Beijing. The president of the council was Yue Zhijian [1471 1807 1017], Vice Minister of State Economic Commission and concurrently Director of the General Standardization Bureau.

Rules and Regulations of Standardized Quality Control Promulgated

Following the Working Conference of National Standardization held in May 1979, the State Council promulgated the "Rules and Regulations Concerning Standardized Control in the People's Republic of China" in July along with the issue of a notice saying that standardization was an important means of organizing modernized production, and an important component of scientific management. It was also said that a successful standardization could play an important role in the high-speed development of the national economy, in improving the quality of industrial and agricultural products and of engineering construction, in raising the labor productivity, and in fully utilizing the state's resources. According to the rules and regulations, products which do not measure up to the standard cannot be included in the output as a fulfillment of state plan; their output value cannot be accounted for; and their shipment from the factory is not permitted. Should any violation of the rules and regulations of standardization produce serious consequences or major incidents, the person responsible for the violation will be criticized, disciplined, fined or even legally persecuted according to the extent of the damage. Should any enterprise fail to produce according to the standard or should it produce goods of inferior quality, the government has the right to refuse to issue a certification. In serious cases, the government has the right to recommend to the departments in charge financial sanctions against the enterprise or the personnel concerned, or the closure of the enterprise for consolidation. The system of using fine quality as a symbol will be enforced and the policy on fine quality will be implemented. Those who have made important contributions in winning outstanding achievements in the production of standardized goods should be rewarded. The implementation of these rules and regulations, and the "Certain Regulations Concerning the Expansion of the Decision-Making Power in Business Management by State-Run Industrial Enterprises" issued by the State Council in July, and the policy of combining the regulative role of planning with that of the market has given a strong impetus to the improvement of enterprise management, the quality of products and the increase of production and practice of economy.

Mineral Resources

[Article by the Ministry of Geology]

Mineral Resources and Geological Work

China has a huge area with wide open seas, variegated geological structures and rich mineral resources. Since the founding of the People's Republic in 1949 and through the painstaking efforts of the geological workers throughout the country, geological survey and research have made great progress. The number of varieties of mineral products, whose deposits have already been verified, and the mineral beds now under industrial evaluation have been increased from 18 in 1949 to more than 130 in 1979. These varieties include ferrous metal, nonferrous metal, auxiliary materials for metallurgy, fuel mineral products, chemical industrial raw materials, building materials and other nonmetallic raw materials, forming a fairly complete assortment. China is one of the few countries in the world with such a complete assortment. The deposits of iron, coal, phosphorus, copper, aluminum, lead, zinc, tungsten, tin, molybdenum, and antimony, which have been verified, were among the foremost in the world and basically sufficient for the several five-year plans after 1953.

We have taken the wrong path in geological work because of our violation of the economic laws and because of the interference and disruption over a long period by Lin Biao and the "gang of four." Geological work is still one of our weak links. The geological departments have changed their methods since the smashing of the "gang of four," and proceeding from realities, they boldly revised the key points for a general geological survey and prospecting. Notable success was achieved in a comparatively short time. In a conference of geological bureau chiefs throughout the country held in January 1980, a special discussion was conducted on the question of further implementing the eight-character policy of the national economy along with a call for the vigorous strengthening of the energy resources, agriculture, light industry, building material industry, chemical industry and the survey and prospecting for mineral resources required for the foreign trade. Energy resources were to occupy the first place in geological work, and a survey should also be conducted for the development of chemical fertilizer resources. The survey and prospecting of nonferrous metals and rare metals should be strengthened, and concentrated efforts should be made in ocean geological work so that a breakthrough could be made in the locations where geological conditions are favorable. At the same time, the geological rank should be consolidated along with the restructuring of the management in order that geological work will actually pave the way for construction and accelerate the accomplishment of the four modernizations by discovering more and better mineral resources.

Coal and Petroleum

Coal. Deposits totaling 600 billion tons have been verified. Anthracite and bituminous coals which include long-flame coal, gas coal, rich coal, coke, lean coal, poor coal, loose coal, brown coal and bone coal, forming a fairly complete assortment, are spread out all over the country. Coal fields are mostly concentrated in the northern part of China including North China, the Northwest and the Northeast. Among them, the one in Shanxi Province is most important, because China's industrial coal is mainly obtained from here. The coal formations in North China mainly belong to the Permian system of the Palaeozoic Era. In the Northwest and Northeast, they mainly belong to the Jurassic Period. In the southern part of China, they mainly belong to the Permian system. The exploitation of coal resources began very early in China, the principal coal mines being located in Datong of Shanxi, Kailuan and Fengfeng of Hebei, Fushun and Benxi of Liaoning, Hegang of Heilonggang, Weibei of Shaanxi, the northern slope of Tianshan Mountains in Xinjiang, Pingdingshan of Henan, and Huainan and Huaibei of Anhui. There are also important coal mines in Guizhou and Yunnan.

Petroleum. China has won great achievements in geological work with regard to petroleum in the past 30 years. In the early 1950's, a number of oilfields were discovered in the western part of China, including Gansu, Qinghai, and Xinjiang. In the late 1950's, the Daqing Oilfield was discovered in Hailongjiang; Fuyu Oilfield was discovered in Jilin; and a number of oil and gas fields were discovered in Sichuan. In the 1960's, successive discoveries of new oil and gas fields were made in Shandong, Hebei, Liaoning, Hubei and so forth. At the same time, oceanic geological work was carried out in the search for oil resources. Since the 1970's, intensified efforts have been made in discovering oil resources from Bohai, Huanghai and Donghai Seas all the way down to the South China Sea. A number of oil and gas fields have been discovered in northern Jiangsu, Shaanxi, Gansu, Ningxia, Guangdong, Henan and the Bohai Bay. In recent years, some industrial oil gas currents were discovered in the Tarim Basin of Xinjiang, in northern and northeastern Sichuan, in Beibuwan [Tonkin Gulf] and the estuary of Zhujiang River [Pearl River].

Metal Mines

Iron Mines. China's iron mines of various sizes are widely spread out over various provinces (regions). Iron mines of the Anshan type (the sedimentary metamorphic type) are the main type in China, and are distributed over the area from Anshan of Liaoning to Jidong of Hebei. This type of mineral can be easily extracted, although their ores are not of a high grade. In Sichuan, there are large mineral beds of vanadium, titanium and magnet spread out in Panzhihua. Besides iron, such important components as vanadium and titanium can be recovered. In Hubei, the "Daye" type of iron mine (formed by the interaction of gas and heat along the contact edges of different layers) in Daye has long been well-known. There are also similar mines in the area to the east of this mine. In the northern and southern parts of China, there are also many iron mineral beds of the sedimentary type, and the mineral layers are mostly of the Sinian system in the north and the Devonian system in the south. In recent years, attention has been drawn to the iron and siderite mineral beds, connected with volcanic activities, which will improve the prospects of new discoveries. In 1979, the total discovered iron deposits in the country exceeded 40 billion tons.

Manganese. China's manganese deposits are among the largest in the world. The origin of these mines dates back to the Sinian and the Triassic Periods, or mostly the Sinian and Devonian Periods. The known manganese mines are located in the central-southern region, especially in Guangxi.

Chromite. These mines are spread out over Northwest China, and the discovered ones are mostly in the geosyncline region of the late Palaeozoic Era. The mines in the east are not large, but larger ones have been discovered in Xizang in recent years.

Copper. China's copper mines are in the top rank in the world. They are spread out mainly in the valleys of the middle and lower reaches of Changjiang River and in the southwestern region. In Northwest and North China, there are also fairly large copper deposits. China has generally all the known varieties of copper in the world.

Lead and Zinc. The mining and utilization of lead and zinc has had a long history in China. These mines are widely spread out, with the ratio of lead higher than that of zinc. From them, some useful components, such as silver, can be recovered. New lead and zinc mines were discovered in the west of Qinling and the western part of Yunnan Province in 1979.

Bauxite. The bauxite mineral beds, which are related to the coal of the Palaeozoic Era and form quite a large proportion of China's mineral resources, are mainly located in Shanxi, Henan and Guizhou.

Tungsten. China's tungsten mines are in the top rank in the world, and are mainly located in Jiangxi and Hunan to the south of the Nanling Mountain Range. Mining has been carried out in these places for many years, but the reserves are still considerable. Other tungsten mines with a promising future have also been discovered in North China and the Northeast Region.

Tin. Tin deposits also rank first in the world. The Gejiu Tin Mine of Yunnan has long been well-known. There are also tin mines in Guangxi, Guangdong, Hunan and Jiangxi.

Molybdenum. China's molybdenum mines rank second in the world and the mineral beds are distributed mainly in the north. With the exception of the silicate type, several of the perphyry type have been verified. The mineral beds in the north of Qinling Mountain and Funiushan Mountain are among the important discoveries.

Nickel. In the late 1950's, an extra large copper-nickel mine, which basically marked a new phase in China's mining industry, was discovered.

Antimony. China's antimony mines are well-known and their reserves are the largest in the world. Approximately one half of the world's antimony reserves are in China. In addition to those located in Hunan, antimony mines have also been discovered in the northern part of China.

Mercury. China's deposits of mercury is also in the top rank of the world. They are mainly located in the "mercury belt" of Hunan and Guizhou, and Guizhou is particularly known as the "Province of Mercury." In recent years, mercury mines of high value have also been discovered in the Qinling Mountainous Region.

Gold. Gold mining has a long history in China. Panning for gold was carried out along the coasts even in ancient times. Gold mines are located in various parts of China, but more concentrated in the Northeast, East China, and the Qinling and Yanshan regions. Gold resources are also rich in Taiwan Province where the famous Jianguashi Gold Mine is located.

Platinum. In the late 1960's, platinum mineral beds related to chromite and nickel mines were discovered in China. In the past several years, many nonferrous and precious metal mineral beds containing associated platinum ores were discovered. In addition, pure platinum mineral beds have also been discovered.

Rare Earth. Rare-earth mineral beds, on which China has done much meticulous work, are mostly intergrowths with iron mineral beds. These beds are large and have rich reserves with light rare earth as the predominant element. Some of them are produced in the phosphorus-forming beds. The known ones are cerium, lanthanum, preseodymium, neodymium, samarium, europium, yttrium, and so forth.

Nonmetallic Minerals

Phosphorus. China is rich in phosphorus resources. There are many such mineral formations, the main ones being of the Sinai and Cambrian Periods. Those of Sinai Periods, located in Hubei, Hunan and Guizhou form one of the important phosphorus basins of the world. Those of the Cambrian Period are also quite extensive, being mainly concentrated in Yunnan, Guizhou and Sichuan in the Southwest.

Magnesite. The magnesite mine in Liaodong Peninsula is quite a large one. China ranks first in the world in magnesite production. Fairly large new magnesite mineral beds were discovered in Sichuan, Shandong and Hebei in recent years.

Sulphur. The mineral products from which sulphur can be extracted in China are vulcanized iron, nonferrous metal, oil and gas associated with sulphur, gypsum, alum, and so forth. At present, China mainly uses iron pyrites and nonferrous metals associated with sulphur. The verified reserves of iron pyrites are now in the top rank of the world. These mines are mainly located in Guangdong, Anhui and Nei Menggol. The majority of these mines were formed from pyrites of the volcanic rock system and others were formed by the interaction of gas and heat in sedimentary metamorphism. In addition, there are large deposits of sedimentary pyrite.

Mica. The verified mica mines are located in Xinjiang, Sichuan and Nei Menggol. The significant mineral ores are imbedded among the gneiss and schists, and belong to the granite-pegmetite type. Their origin is mostly related to the infiltration of acid into the rocks during the Varician Period. The main mica producing area is the Altai Region in Xinjiang.

Asbestos. China's asbestos mines are mainly located in Qinghai and Sichuan, and the important types are the serpentine asbestos related to the ultra basic rocks. In addition, there are in the eastern part of China certain asbestos mines among the carbolic acid rocks which contain magnesite, but these mines are not large.

Kaolin. The name "kaolin" [meaning high mountain range] is derived from the place of its production. The kaolin produced in Jiangsu has a long history and is famous at home and abroad. These mines are located all over China, but the principal ones are in Jiangxi and Hunan.

Graphite. These mines are distributed in north China, the northeast, and Shandong Province, and mainly belong to the sedimentary metamorphist type. The mineral beds are located among the ancient gneiss, chists and Dali rocks. The graphites look like fish scales and are of fine quality. The graphite produced in Shandong is selling well abroad. New graphite producing areas have been found in recent years.

Gypsum. Except for the northeast, gypsum is produced in various parts of the country. The mineral layers mainly belong to the Triassic and the Tertiary Periods. The Yingcheng gypsum produced in Hubei has a long history and is of fine quality. In recent years, a large hard gypsum formation was discovered among the Triassic layers. In 1979, in particular, a large gypsum bed was discovered in Shaanxi.

Sodium Bentonite. This has been recently discovered in Zhejiang, Xinjiang and Jilin.

Precious stones and jade. Hotien jade is famous at home and abroad. In Henan, there is the Nanyang jade; in Liaoning, the Xiuyan jade; in Qingtian, the pyrophyllite, which is called Qingtian stone; in Hubei, the Turquoise; in Henan, the Hujing [tiger's eyeball] stone; and in Fushun, the black amber. In addition, there are crystals, smoke-crystals, purple crystals and amber produced in various parts of the country. In Liaoning, Hunan and Shandong, there are diamonds. Beijing jade is also called "fencui."

Coal Industry

[Article by Huang Fengchu [7806 1144 0443]]

General Description

China has rich coal resources which form a complete assortment and are widespread. Among the 29 provinces, municipalities and autonomous regions on the Mainland, 27 of them have their own coal resources in varying amounts. By the end of 1979, the verified coal reserves amounted to some 600 billion tons with an annual output of

635 million tons or an increase of 2.8 percent over that of 1978. China occupies the third place in the world in coal production. Out of this output, some 54 million tons of dressed coal are used to support industry. The quality has been improved. The commodity coal, under the system of unified distribution, contains an average of 22.5 percent of coal ash and 0.64 percent of gangue. These contents have been lowered by 0.86 percent and 0.26 percent respectively as compared with those of 1978. Its quality in 10 provinces and 35 coal administration bureaus has been raised by one grade since 1978.

China has a long history of coal industry. However, because of its weak economic foundation, its annual output has been only about 32 million tons, 10th in the world, up to 1949, the year of national liberation, despite its rich resources. Since liberation, however, coal industry has undergone great development. By 1979, there were more than 2,000 coal mines operated at or above the county levels, by more than 4 million workers and staff members. There are 11 large mines with annual outputs above 10 million tons and 13 mines with annual outputs ranging from 5 to 10 million tons. Among the 2,137 counties in the country, 1,221 of them have built their own local mines.

Yet the development of coal industry is lagging behind the national economic development, and within the coal industry itself, mining and tunneling are somewhat disproportionate. In 1979, the coal industrial sector firmly upheld the principle of making readjustment on the one hand and increasing production and practicing economy on the other. The coal output exceeded the quota of the state plan when the work of readjustment began.

Construction of Eight Major Coal Bases Speeded Up

In his report before the First Session of the Fifth National People's Congress, Premier Hua Guofeng proposed the construction of eight major coal bases. In 1979, construction of these eight bases began systematically.

The eight major coal bases are: Huainan and Huaibei Mines of Anhui Province (called the "Two-Huai Coal Base" for short); the Yangzhou mine of Shandong Province; the Xuzhou Mine of Jiangsu Province, which is also called the Feng (county), Pei (county) and Tong (shan county) coal base; the Kailuan Mine of Hebei; the Datong Mine of Shaanxi; the Pingdingshan Mine of Henan; the Lu (zhi) Pan (county) Shui (Cheng) Mine of Guizhou; and the Huolinghe Mine of Nei Menggol Autonomous Region. The coal reserves of these eight major bases have been verified as being more than 120 billion tons. In 1979, the task of building these eight major bases amounted to one-third of all the capital construction tasks for the coal industry in the country.

Among these eight major coal bases, Kailuan, Datong, Pingdingshan and Xuzhou Mines are the old coal producing centers of China supplying huge quantities of coal for the state. New construction, expansion and alterations were continued in 1979. In Kailuan Mining Area, for example, a large mine shaft with a designed capacity of 4 million tons--the Qianjiaying Mine--and the Linnancang Mine with a designed capacity of 1.2 tons, were newly built. In Datong Mining Area, the building of a new mine, the Yanzishan shaft, with a designed capacity of 4 million tons, also began in 1979. In Pingdingshan Mining Area, the No 8 mine with a designed annual output of 3 million tons is now under construction. Finally, in the Feng-Pei-Tong Mining Area, the building of two pairs of shafts with an annual output of 3 million tons is now beginning. Here, a coal dressing plant is also being built as a preparation for the supply of more dressed coal for the Baoshan Iron and Steel Complex.

Huainan, Huaibei, Yangzhou and Huolinhe Coal Mines are the newly built major coal bases in China.

Huainan and Huaibei Coal Bases are located in the broad plain north of Huaihe River in Anhui Province. The known coal reserves in these mines are more than 22 billion tons. The coal formation is thick and the quality is good. In the past several years, more than 70,000 workers and technicians from various parts of China have come here to help build these bases. At present, work has already been started on eight pairs of shafts with a total designed capacity of 15 million tons. The building of five large coal dressing plants has already been planned and work on one of them with a designed capacity of 1.8 million tons has already been started. Construction of highways, a two-level railway bridge, and railways passing through the mining area are proceeding in earnest. The engineering jobs of power transmission and transformation and the building of workers' dormitories, stores and schools are all under way.

The Yanzhou Coal Base is located in the southeastern part of Shandong and occupies an area of more than 3,700 square kilometers. It has rich coal reserves and thick coal formations, with gas coal and rich coal of low sulphur and low ash contents as the main features. These are fine quality coal for producing power and for coking. In 1979, more than 23,000 workers and staff members assembled here to start work on three main shafts with a total designed capacity of 10 million tons. Four pit shafts of one of them, the Xinglongzhuang Mine, have already reached the bottom, and 63 percent of the work on the tunnels and 74 percent of that on the ground surface as designed have been completed. The main shaft and the north-south ventilation tunnel of Baodian Mine, with a designed capacity of 3 million tons, have also been completed.

The Huolinhe coal base is the largest opencut mine in China. The annual designed capacity is 10 million tons in the early stage and 20 million tons in the late stage. It was designed jointly by two companies of the Federal Republic of Germany, and modernized equipment and methods for coal extraction will be used in the entire base. At present, more than 10,000 workers and staff members have gathered together in the central area of the coal field and are putting up the power plants, material processing plants, vehicle repair plants, cement factories, warehouses and other auxiliary projects. The Tong-Huo Railway of more than 400 kilometers will soon be open for traffic.

Completion of a Large Modern Coal Mine, the Sangshuping Coal Mine

The building of Sangshuping Coal Mine, a large modern coal mine in China, was successfully completed in November 1979. It has been formally commissioned.

The Sangshuping Coal Mine is a large mine designed, built and equipped by China itself. The designed annual capacity is 3 million tons. There are five coal mining areas and 12 work sites below the shaft and extraction is mechanized. Surface transportation, loading, storage and other links of production are all automatically controlled. Facilities for the workers' daily life and the welfare measures are fairly complete. In addition to the workers' dormitories, clubs, stores, schools, mess halls, hospitals and childcare centers, there is a joint service building with a total floorspace of 12,000 square meters. Inside this building are spacious bathing pools, gymnasiums equipped with sun lamps, changerooms and light control rooms. This shows the concern of the party and the state for the miners.

There are rich coal resources in the north of the central plain in Shaanxi. This region is called the "Black Belt North of Wei River." Sangshuping Coal Mine is located at the eastern tip of this belt inside Hancheng County. It is close to Huanghe River and is also accessible by highways and railways. The coal reserves here are rich and the coal has high caloric value, low ash contents and is good for the power industry.

Mechanized Coal Mining Teams Rewarded by Ministry of Coal Industry

In 1979, there were altogether 560 mechanized coal mining teams (commonly referred to as 487 mechanized coal mining teams and 73 comprehensive mechanized coal mining teams) for all the coal mines under unified state control. These mechanized coal mining teams produced 96.31 million tons of coal, or 32.45 percent of the total output of these state-controlled mines in that year.

In 1979, the Ministry of Coal Industry rewarded 130 advanced mechanized coal mining teams, classified as A, B and C teams. Among these 130 coal mining teams, there were 108 ordinary mechanized mining teams, and the one with the highest output was the Third Mining Team of Wangfeng Mine under the Jiaozuo Coal Administration Bureau. Its annual output was 563,509 tons, being three times that of the other ordinary mechanized teams. The Ministry of Coal Industry also rewarded 22 comprehensive mechanized mining teams, and the one producing the highest output was the Third Team of Qishan Mine under the Xuzhou Mining Administration Bureau. Its annual output was 631,562 tons.

The Ministry of Coal Industry awarded the advanced mechanized coal mining teams certificates of merit and banners, and commended them for their creative labor and great achievements.

Petroleum Industry

[Article by Yu Youhai [0060 2589 3189]]

General Description

The petroleum industry has undergone great development since the founding of the People's Republic. In 1979, the total national oil output was 106.15 million tons, a 2-percent increase over that of 1978, and in the ninth place among the oil producing countries of the world.

In 1949, when New China was born, the national output of crude oil was only 120,000 tons (not including that of Taiwan Province. Same as follows.) In 1979, the annual output of crude oil was more than 881 times that of 1949, with an average progressive increase of 25.4 percent each year. Because of the development of the petroleum industry, China became basically self-sufficient in oil in 1963 and began to export oil in 1973. Thus China has become an oil exporting instead of an oil importing country.

By now, China has built more than 10 bases for the production of oil and natural gas, such as Daqing, Shengli, Jizhong, Dagang, Liaohe, Henan, Karamay, Yumen and Sichuan.

Instead of being limited to Gansu, Xinjiang, Shaanxi and Sichuan as it had been before the liberation, the source of oil supply was extended to 19 provinces, municipalities and autonomous regions. The number of workers and staff members engaged in the oil industry was also increased from 11,000 to 1 million.

China's outputs of crude oil and natural gas was increased and the economic and technical targets were also satisfactorily fulfilled in 1979. For example, the water content of the exported oil was reduced from 0.69 percent in 1978 to 0.48 percent; and the consumption index of fuel for processing every ton of crude oil was reduced from 38.43 kilograms in 1978 to 33.66 kilograms. The general labor productivity was increased from 53,820 yuan in 1978 to 55,003 yuan. From 1950 to 1979, the total amount of profits handed over and taxes paid to the state was 3.2 times the total state investments on the petroleum industry.

The Rapidly Developing Oil Refinery Industry of China

Along with the increase of crude oil output, particularly since the opening of the Daqing Oilfield, China's oil refinery industry has also developed rapidly. Shortly after the founding of New China, there were only a few oil refineries in the country, such as those in Yumen of Gansu and Fushun and Dalian of Liaoning. Now there are oil refineries in 21 provinces, municipalities and autonomous regions. In 1979, the plan for processing crude oil was overfulfilled.

The production of gasoline, kerosene, diesel oil and lubricant oil, among others, has not only reached the planned quota, but also fulfilled the task of increasing the output of each item by 1 million tons in 1979. The total output of these four major categories of products was 5.5 percent above that of the previous year. At the same time, compared with those of 1978, the output of aviation gas was increased by 21.8 percent and that of light chemical industrial oil increased by 40 percent. Other oil outputs have also increased by varying degrees. As a result of the campaign to increase production and practice economy, the comparable product costs in the whole trade were reduced by 1.48 percent, which means a saving of 125 million yuan of state funds.

The quality of refined products in 1979 also showed improvement. The grand total of 918 varieties of oil products turned out by the key refineries in 1979 was the highest in history, and 304 of them, an increase of 102 over the previous year, reached the advanced levels in the country; while 143 of them, an increase of 47 over the previous year, reached or approached the world standards. The No 3 jet fuel of Oil Plant No 7 and the No 45 transformer oil of Dushanzi Oil Refinery were awarded gold medals from the state, while the No 46 anti-corrosion turbine oil was awarded a silver medal. In addition, another 33 varieties of oil products from 22 enterprises were rated as fine-quality products.

Sustained Increase of Output by Daqing Oilfield

Daqing Oilfield is the largest comprehensive petrochemical industry complex in China. In 1979, this oilfield produced more than 50 million tons of crude oil, and the production targets set in the state plan were fulfilled.

Beginning from May 1960, the average output of crude oil by Daqing Oilfield was increased at an average progressive rate of 28 percent annually. The development was very fast. Normally, an old oilfield like this, which has been in operation for more than 10 years, should have a progressively reduced output. To solve this problem, the workers of the oilfield has since the early days of operation used the method of internal water injection to maintain the pressure in the oil formations and then, in the later stage, the method of water injection and oil extraction layer by layer. Their technique occupied a leading position in the history of oilfield operation in the world. At present, the pressure in the oil layers is even higher than before, and none of the spurting wells has ever stopped spurting. The average daily output is higher than that of the early days, and the whole oilfield continues to maintain its high and stable yield.

Along with the high and stable yields of crude oil and natural gas, the processing of crude oil, the petrochemical industry and other productive undertakings in Daqing Oilfield in 1979 also underwent new developments, and the labor productivity of the entire personnel exceeded 60,000 yuan, an all time high for the oilfield. From 1960 to 1979, the total amount of profits and taxes to the state from Daqing Oilfield was 17.8 times the total amount of state investments in this oilfield.

In 1979, the living conditions of workers and staff members of Daqing Oilfield were also improved. There were 133 newly built residential houses with a total floorspace of 400,000 square meters, and 6,700 families of the workers and their dependents have gradually moved into their new homes.

Liaohe Oilfield, A Large Oil and Gas Field, Completed

In Liaoning, the base of heavy industry in China, a large oil and gas field--the Liaohe Oilfield--was completed in 1979. According to its present productive capacity, this oilfield can produce 5 million tons of crude oil and 1.7 billion cubic meters of natural gas annually. It has become one of the principal oilfields in China.

Liaohe Oilfield is located between Shenyang, Yingkou and Jinzhou in Liaoning Province and is accessible by railways and highways from all directions. By the end of 1979, more than 1,800 wells had been sunk in the oilfield, and more than 160 stations for storing and shipping out the gas had been established. It now consists of eight completely equipped oil extraction centers. Its completion and commission will bring the local iron and steel industry, oil refining industry and chemical fertilizer industry closer to the source of crude oil and natural gas supplies. It will play a very significant role in further developing the role of Liaoning as an old industrial base. The reserves of oil and gas in Liaohe Oilfield are fairly abundant. The oil-bearing formations are thick and there is a large variety of oil and gas deposits. The quality of the crude oil is fairly good, with low sulphur content and a higher proportion of light oil.

The exploitation and building of Liaone Oilfield began in 1970. Because of the interference and sabotage by Lin Biao and the "gang of four," and its location in marshland, the oilfield was confronted with many difficulties. After the smashing of the "gang of four" and particularly after the Third Plenum of the 11th Party Central Committee, the construction began to gather momentum, and by 1979, the productive capacity of crude oil was newly increased by 50 percent, while the output of crude oil was actually increased by 27 percent over that of 1978. In 1979, the newly completed Huanxiling Oil Extraction Area was able to produce 1.39 million tons of crude oil, because it was built in a scientific way and completely equipped for oil and gas extraction, water injection and with electricity supply, highway transportation and facilities for the treatment of polluted water.

In the course of its building, the leadership of the oilfield paid great attention to the living conditions of workers and staff members and organized their dependents to reclaim land and to develop agricultural and sideline production. The building of workers dormitories, hospitals, schools, stores, childcare centers and other daily life facilities in all oil areas are now in progress.

High-Speed Construction and Commissioning of Nanyang Oilfield

The site of Nanyang Oilfield was discovered in a small depression of the geological structure. This discovery has helped emancipate people's minds and open a broad vista for oil prospecting in small and medium-size basins.

Located in the southwestern part of Henan, Nanyang Oilfield is the first oilfield built in the central-southern region where the scarcity of oil resources was well-known. Prospecting began in 1970, followed by construction in May 1977. Carrying forward the fine tradition of the Daqing workers in overcoming difficulties and tapping potentials, they succeeded in building the oilfield as a productive source, putting it into operation, and handing over profits to the state all in the same year. By 1979, there were in the oilfield hundreds of oil wells and water injection wells, more than 850 kilometers of pipelines of various types already laid, four combined transportation stations, 38 measuring stations, two long oil pipelines measuring hundreds of kilometers, and a large number of engineering projects. Oil from this oilfield is carried through long pipelines to refineries, some chemical fertilizer plants and other enterprises. This oilfield has made important contributions to industrial and agricultural developments in the Central Plain and South China.

New Achievements of China in Oil Prospecting

To look for new resources of oil and gas, China devoted more manpower to oil prospecting and completed more work in 1979 than in any previous year. Its achievements in that year were remarkable.

In the southwestern part of Qaidam Basin of Qinghai Province, a new oilfield with rich reserves was discovered. Out of the 26 exploratory wells sunk, 20 of them have shown oil-bearing formations and two of these wells which had been under trial extraction for 1 year and some 4 months respectively, are each producing more than 100 tons of oil and 10,000 cubic meters of natural gas daily. According to the data of prospecting, the underground pressure is high; the geological structure is favorable; the crude oil is light; and the output is high. The new oilfield has great assets for future exploitation.

In the Tarim Basin in the southern part of Xinjiang, three high yielding oil and gas wells were sunk. According to the conditions of spurting as observed over a long period, there is huge underground pressure and the output is quite steady. The output of each well is hundreds of tons of crude oil and over 10,000 cubic meters of natural gas. Tarim Basin has an area of 560,000 square kilometers, which is more than the combined areas of Shandong, Henan, Anhui, Jiangsu and Shanghai. The conditions of these three high-yield wells indicate the rich oil and gas resources in this huge basin. There is a good future for oil geological prospecting here.

An oil well of industrial value has been sunk in the basin at the estuary of Zhujiang River in the South China Sea, and in Sichuan, prospecting for natural gas is being continued.

China's geological workers, engaged in oil prospecting, are now working in North China, Northeast China, East China, Northwest China, Central-South China, and Southwest China in addition to the continental shelves and along the coast, and have made many new discoveries of oil and gas resources.

Power Industry

[Article by Ding Genxi [0002 2704 0823]]

General Description

In China, 281.95 billion kwh of electricity were generated in 1979, a 9.9 percent increase over that of 1978. This figure of generation was then the seventh highest in the world. By the end of the same year, the installed capacity reached 57,225,400 kilowatts, the eighth highest in the world.

Such an achievement was attributed to the efforts of the broad masses of workers and staff members of the electric power departments who had, for 30 years, labored under trying circumstances created by the extremely backward electric power industry in Old China. The power generated in 1979 was 64 times that of 1949, and the installed capacity was 31 times that of Old China. The geographic distribution of electric power industry has undergone very great changes. In addition to the Northeast, North China, East China, Beijing, Tianjin, Shanghai and other coastal areas, many large and medium-size power plants have been built in the Central-South, the Southwest, the Northwest and even in the remote frontier and mountainous regions. By the end of 1979, there were in China 2,847 power plants each with a generating capacity of 500 kilowatts or more. Among them, 1,528 were hydropower plants and 1,319 were thermopower plants. There were 68 large power plants with installed capacities of more than 250,000 kilowatts, and their combined installed capacity amount to more than 50 percent of that of the whole country. Among the large thermopower plants are the Qinghe Power Plant of Liaoning, Wangting Power Plant in Jiangsu, Tangshan Power in Hebei, Shijingshan Power Plant of Beijing, and Qingshan Power Plant of Hubei. Among the large hydropower plants are Liujiaxia Hydropower Plant of Gansu, Danjiang Hydropower Plant of Hubei, Gongzui Hydropower Plant of Sichuan, Xinanjiang Hydropower Plant of Zhejiang, and Zhesi Hydropower Plant of Hunan. These hydropower plants are distributed along the valleys of Huanghe River, Hanjiang River, Daduhe River, Xinanjiang River, and Zishuihe River. There are also thousands or tens of thousands of small hydropower plants scattered over the broad rural and mountainous areas.

Power industry is a big coal consumer and the amount of coal burned in this industry amounts to more than one-sixth of the coal output every year. A large amount of electricity is also consumed by the power industry itself. In 1979, the electric power departments popularized some new techniques for coal and power conservation, and for transportation and fuel control. The amount of standard coal to be consumed for the production of each kwh of electricity generated by thermopower plants of more than 6,000 kilowatts throughout the country was reduced by 12 grams below that of 1978. Thus in the year 1979, 4 million tons of coal and 1.54 billion kwh of electricity were saved.

According to statistics, more than 1,004,100 workers and staff members were engaged in the power industry in 1979; the total output value reached 16.14 billion yuan; and the profits handed over to the state totalled some 4,982 million yuan. From the time of the founding of the People's Republic to the end of 1979, an amount of 63.43 billion yuan was handed over to the state from the power industry as a contribution to China's socialist construction.

China's Power Grid

A power grid stands for a combination of the power generating plants, power transformer substations, power transmission lines and power distribution lines, for the generation and supply of electricity. Along with the developments in the construction of hydropower and thermopower plants, and the enlarged scope of power supply, China's power grid has continued to expand. By the end of 1979, 20 power grids of more than 500,000 kilowatts were formed. Among them were the Beijing-Tianjin-Tangshan power grid, the East China power grid, the Northeast power grid, the Shaanxi-Gansu-Qinghai power grid, the Central China power grid, the Shandong power grid, the Shanxi power grid, the Sichuan power grid, the Guangdong power grid, the Central-Northern Hunan power grid, the Southern Hebei power grid and the Guiyang power grid, totalling 12, and each with an installed capacity of more than 1 million kilowatts. The combined installed capacity of the 20 power grids accounted for 83 percent of that of the whole country. Hydropower and thermopower supplemented each other in timely adjustments within the power grids, which also strived for the rational use of fuel and the reduction of consumption. The different regions supported one another by supplying to one another's needs. Safety in power generation and supply is guaranteed and the requirements for industrial and agricultural production and the people's daily life will also be taken care of. Even though there may be destruction in the event of war, power supply can be speedily restored.

To further strengthen the centralized control of the power grids, the North China, Northwest China and Central China Power Industry Administration Bureaus were established in addition to the original two in Northeast and East China, with the approval of the State Council. Since January 1980, the North China Power Industry Administration Bureau has taken over overall controls of power generation in North China and the Northwestern regions. This will create the conditions for further expansion of the power grid of Northwest Region and the full exploitation and utilization of energy resources. The Southwest Power Industry Administration Bureau is now in the process of establishment.

By 1979, all power grids had restored their normal cycle operation. In the previous years, administration of the power industry was chaotic because of the interference and sabotage by Lin Biao and the "gang of four," and the cycle operation in the East China and other large power grids was seriously low, causing serious damage to industrial and agricultural production. Since the smashing of the "gang of four," the power industry departments in various localities have paid great attention to capital construction and the improvement of their existing equipment through maintenance and repairs, and achieved 93 percent efficiency for their power generating equipment. At the same time, they stepped up their efforts in the planned use of electricity and in electricity conservation, and thus enabled the power grids to gradually restore their normal cycle operation despite fairly serious shortage of power. According to statistics compiled on the East China power grid, some 800,000 kwh of electricity, the amount generated by 450 tons of coal, has been saved each day as a result of the raised voltage following the restoration of normal cycle operation.

More Than 40 Power Generation Projects Newly Completed in 1979

In 1979, China's Power Industry Departments newly completed 41 large and medium-size hydro- and thermopower generation projects, newly installed 53 generating units with a total installed capacity of 4.09 million kilowatts, and overfulfilled the state's plan of power generation.

Some of the newly completed thermopower generation projects and newly commissioned thermopower generating units were large "pit-mouth" power stations close to coal mines. These are, for example, the Xuzhou Power Plant of Jiangsu, Jiaozuo Power Plant of Nenan, Matou Power Plant of Hebei, Shentao Power Plant of Shanxi, Hancheng Power Plant of Shaanxi, and Shiliquan Power Plant of Shandong. In the Xuzhou Power Plant, built near the Xuzhou Mining Administration Bureau, four sets of 125,000 kilowatt generating equipment have been completed, installed and commissioned by December 1979, and are daily transmitting some 7 million kwh of power for the East China power grid. They are playing an important role in easing the power shortage in Jiangsu and East China regions.

The newly completed hydropower stations and the newly commissioned hydropower units included the Wujiangdu Hydropower Station and the Maotiaohe "Five-stage" Hydropower Station of Guizhou; the Hunanzhen Hydropower Station of Zhejiang; the Taipingxiao Hydropower Station of Liaoning; the Xierhe One-Stage Hydropower Station of Yunnan; the Huaan Hydropower Station of Fujian; and the Niululing Hydropower Station of Hainan Island. The Wujiangdu Hydropower Station of Guizhou is located near the natural barrier where the Red Army forced the crossing of Wujiang River many years ago. Its designed capacity is 630,000 kilowatts. Its main dike is 368 meters long and 165 meters high, and is the highest one basically completed in China. The first set of 210,000 kilowatt water turbine generating units was completely installed and began to generate electricity on 28 December 1979.

In 1979, acting in accordance with the policy of national economic readjustment, the Ministry of Electric Power Industry and the various provinces, municipalities and autonomous regions rearranged their original power projects according to their sizes and relative urgency, and had to halt or postpone a number of them which were unrealistic in terms of construction possibility in order to protect more than 40 key projects, which must be continued, by concentrating the manpower and financial and material resources. Thus these projects were completed, started operation on schedule, and produced the expected results in the same year.

In addition to the Gezhouba Hydropower Station of Hubei and Longyangxia Hydropower Station of Qinghai, there are also other large hydropower stations under construction, such as the Ankang Hydropower Station of Shaanxi and the Baishan Hydropower Station of Songhuajiang River, each with an installed capacity of approximately 1 million kilowatts.

Gezhouba--the Largest Water Conservation Project in China

Construction of the first giant multiple-purpose project on the Changjiang River--the Gezhouba Project--is now being speeded up.

This project is taking place at the estuary of the Xiling Gorge, one of the three gorges of Changjiang River, and 2.3 kilometers below Nanjinguan within the city limits of Yichang. After passing by Nanjiangguan Pass, the river takes a sharp turn from the east to the south, and its width increases from 300 to 2,300 meters. The flow then becomes slower. There are two small islets in the river--Gezhouba and Xiba--and these islets divide the river into three waterways known as the main, second and third channels. Gezhouba is where the gigantic project takes place.

The Gezhouba multi-purpose power station will have a total installed capacity of 2,715,000 kilowatts, and an average annual output of 13.9 billion kilowatt hours.

After completion, it will greatly ease the serious shortage of electricity in the central-southern region.

The Bezhouba project was divided into two stages. The first stage included the construction of two navigation locks and a scouring sluice with six gates on the third channel, and the installation of seven power generating units with a total capacity of 965,000 kilowatts and the construction of a spillway with 27 gates on the second channel. Construction in this stage calls for 70 million cubic meters of earth and stones to be dug out and later to be used for filling holes, and the pouring of 5.73 million cubic meters of concrete. By the end of December 1979, 80 percent of the construction had been completed. The main dam had approached its designed height, while the second and third navigation locks and the scouring sluice with six gates had been basically completed. The dam leading to the entrance of the power station has already reached a height of 68 meters; the first generating unit is being installed; and of the 27 gates of the spillway, 19 have been completed.

This project is undertaken by the No. 330 Engineering Bureau. The construction has been gathering momentum in the 3 years after the smashing of the "gang of four," thanks to the efforts of the broad masses of workers and staff members. The construction task was overfulfilled every year.

Damming Project of Longyangxia Hydropower Station

A large hydropower station with an installed capacity of 1.5 million kilowatts is now under construction at the trunk of the upper reach of China's Huanghe River. This is the Longyangxia Hydropower Station, another large power station constructed on Huanghe River after Liujiaxia and Qingtongxia hydropower stations.

On 29 December 1979, the damming of Huanghe River was successful and the construction of the power station entered a new phase--the large-scale work on the main project.

Longyangxia hydropower station is located in a gorge of the same name in Gonghe County, Qinghai Province, 2,600 meters above sea level. After passing the large grassland in Qinghai Province, Huanghe River enters a 40-kilometer gorge. Here the river is only some 30 meters wide, but the average flow for many years has been only 640 cubic meters per second. Water resources are very rich and the river water has low sand content. The project includes the building of a 172-meter high dam, a reservoir with a capacity of 24.7 billion cubic meters, and the installation of five single-unit generating sets of 300,000 kilowatts. After completion and being put into operation, the electricity generated will be transmitted to two industrial cities, Xining and Lanzhou, and the other areas within the Northwest power grid. This will be a great contribution to socialist construction in the northeastern region.

Construction of Longyangxia Hydropower Station formally began in 1976. In 1979, this project was taken over by the Fourth Engineering Bureau of the Ministry of Electric Power Industry. With a concentration of manpower, and financial and material resources, a 661-meter long, 16-meter high and 15-meter wide tunnel has been excavated to divert the water from the river, and on 29 December 1979, the water flow in the river was successfully cut. Thus the formerly deserted area near the estuary of Longyangxia is growing up as a new industrial town with buildings of more than 300,000 square meters and a population of more than 20,000.

Two 500,000-Volt Ultra High Voltage Transmission Line Put Up

In October 1979, the first 500,000 ultra high voltage transmission line--the Pingdingshan-Wuhan Line--was erected.

This line starts from Pingdingshan, the coal base of the central plain, and ends at Wuhan, the industrial city of Hubei, after crossing the southwestern part of Henan, the northern plain of Hubei and the rivers of Shahe, Baihe, Hanshui and Changjiang. Its total length is 610 kilometers.

The function of this line is to increase the safety and stability of the Central China power grid and to insure power supply for the 1.7-meter rolling mill of Wuhan Iron and Steel Company. Parts of the equipment for this line were imported from France, Sweden and Japan. At present, 60 percent of the foundation has been poured with concrete; 10 percent of the towers has been erected; and the ground for building three transformer substations for the ultra high voltage line has also been leveled.

At about the same time, China put up another 500,000 ultra high voltage line for the transmission of electricity from the power station in the coal base of Yuanbaoshan in Liaoning to the industrial base of Liaoyang. This line is 380 kilometers long, and the work of putting it up started in the winter of 1979. The required equipment for this line was manufactured in China.

In the past, the highest voltage for the transmission lines built in China was only 330,000 volts. The 500,000-volt ultra high voltage transmission line is the highest ever produced in New China.

Vigorous Development of Small Hydropower Stations in China

Along with the development of socialist construction, the small hydropower undertakings have also vigorously developed. By the end of 1979, there were more than 90,000 small hydropower stations in the country with a total installed capacity of 6.34 million kilowatts. By 1979, the total installed capacity was increased by 1.07 million kilowatts. The combination of small hydropower stations with the state's power grids have enabled 86 percent of all people's communes and 60 percent of all production brigades in the country to use electricity.

China has rich water resources, and its water energy reserves rank first in the world. In addition to the large hydropower stations built by the state on Changjiang, Huanghe, Zhujiang and other large rivers, tens of thousands of small power stations have been built on the small rivers by the counties and people's communes in various provinces, municipalities and autonomous regions. This particularly true of the southern part of China where the river valleys are narrow, the waterflow is rapid, and the water drop is great. All these are favorable conditions for small hydropower stations. According to statistics, more than 1,500 of the 2,000 and more counties in the country have built their own small hydropower stations to help in irrigation, drainage, processing agricultural and sideline products, lighting and county- and commune-run industries in the countryside by providing low-cost electricity.

Small hydropower station refers to those with an installed capacity of 12,000 kilowatts or less, or a single-unit installed capacity of 6,000 kilowatts. They use locally available water resources, require simple equipment and less investments, and can be easily built. Hence their rapid development. In Xizang, for example, there was in the past only one 18 kilowatt small hydropower station; now there are 424 of them with a total installed capacity of more than 45,000 kilowatts. In Rongxian County of the southeastern mountainous region of Guangxi Zhuang Autonomous Region, all 13 communes have used electricity since the completion of 250 small hydropower stations. In January 1980, the Ministry of Water Conservancy, the People's Bank of China, and the Agricultural Bank of China jointly held an on-the-spot meeting of small hydropower stations in China to further develop this undertaking.

Several New Energy Sources Used for Power Generation in China

Electricity from wind. By the end of 1979, China's largest experimental generating unit with the use of wind energy had already had more than 2,000 hours of normal operation. The electricity generated was used for lighting, for desalination of sea water and for pumping water, and has played its role in promoting fishery.

This experimental unit was installed on Sijiao Island. With an installed capacity of 18 kilowatts, this unit was jointly designed and installed by the East China Electric Power Designing Institute, the Shanghai Municipal Engineering Designing Institute, the Zhejiang Hydropower Designing Institute, the Zhejiang Provincial Mechanical Science Research Center, the Shaoxing Food Machinery Plant and the Zhejiang Provincial Electric Power Department.

Sijiao Island is located in the east of Hangzhou Bay among the Shengsi Islands to the southeast of the estuary of Changjiang River, where there is always a strong wind with a velocity of 7.1 meters per second, and a force 3 wind for at least 300 days a year. This set can generate electricity with a force 3 wind and will be in full operation with a force 5 wind or more.

The use of wind to generate electricity has the advantage of being pollution-free. Since 1976, China has been studying the utilization of wind force for power generation. By the end of 1979, more than 200 generators turned by wind and each with a capacity of 100-250 watts, have been installed on the grassland of Nei Menggol. They will provide lighting for the yurts, and supply power for movie and electric fences.

Geothermal Power Generation

China has very rich geothermal resources. According to statistics, hot springs have been discovered in more than 2,000 different places. The result of prospecting by the geothermal utilization research departments in more than 30 geothermal areas in Xizang, Yunnan, Guangdong, Fujian and 10 other provinces, municipalities and autonomous regions shows rich reserves of geothermal resources over extensive areas.

Generation with geothermal resources requires no coal or other fuel. From 1970. when research began on the use of geothermal resources for power generation, to 1979, seven experimental stations have been established in China. The largest among them is the Yangbajing Experimental Geothermal Power Station in Xizang, with an installed capacity of 1,000 kilowatts. Work has been going on there to install two generators of 3,000 kilowatts each, and one of them will be ready for operation by the end of 1980. There are also six other experimental geothermal power stations in Huitang of Hunan, Huailai of Hebei, Yichun of Jiangxi and other parts of China. Among them, the one in Hunan is the best. This station has been in regular operation for a long time, and the hot water obtained after the generation is used for pharmaceutical and agro-scientific research, for nursing young plants in hothouses, and for field irrigation. Instead of incurring any loss, these experiments have even produced great profits for the state.

Generation with Tidal Energy

Tidal energy power stations are operated through the utilization of tidal force. According to an estimate, the total resources from tidal force along the coast of China is enough for a total installed capacity of 110 million kilowatts, and the force which can be harnessed and utilized can supply 31-35 million kilowatts.

Experiments on tidal power stations began in 1958. By the end of 1979, the stations already commissioned were: the Rushan power station of Shandong, with an installed capacity of 300 kilowatts; the Jingang Power Station in Shandong, with an installed capacity of 165 kilowatts; the Xiaoshashan Power Station of Zhejiang, with an originally installed capacity of 40 kilowatts, now increased to 200 kilowatts; and the Xiangshan Power Station of Zhejiang with an installed capacity of 100 kilowatts. The completion and operation of these power stations are supporting local agriculture and fishery.

Tidal generation requires no fuel and is pollution-free. It is also suitable for comprehensive utilization in developing the breeding of fish and prawns, in marine chemicals industry, and so forth.

New Technological Achievements in Power Industry

In 1979, three new achievements in China's power industry were passed by the State Scientific and Technological Commission as new inventions. They are: directions for the preparation and application of epoxy emery coating for resistance against abrasion by sands, to be used for hydropower machinery (including water turbines and water pumps); directions for the preparation and application of an abrasion-proof coating compound for hydropower machinery; and the equipment for hydraulic interlocking control of the TFW-400 model pressure adjustment valve. These scientific and technological achievements are now serving hydropower stations with remarkable results.

In Huanghe River of China, each cubic meter of water contains an average amount of 37 kilograms of sands. Even the water from the upper reach contains approximately 10 kilograms. Therefore, the water turbines used by the hydropower stations and the water pumps used by the irrigation and drainage pumping stations along the river are usually damaged through friction with the sands. Such damage inevitably causes the shutdown of the hydropower station for repair by welding. In 1976, when the No 1 water turbine of the Qingtongxia Hydropower Station was damaged, the overhaul took more than 3 months, and more than 2,100 kilograms of stainless welding rods, costing more than 42,000 yuan, were used in repairing 4 propeller blades. To solve this problem, the Research Institute of the Huanghe Water Conservancy Committee and the Research Institute of the Tianjin Surveying and Designing Institute invented the new technique of epoxy emery coating. In repairing the propeller blades of the water turbine, no welding is required, because an application of the coating according to the specified way will suffice. Thus for each repair, the time can be reduced by 90 percent and the expenses reduced by 95 percent.

The use of abrasion-proof nylon coating compound is another new way to prevent damage from the same source. This is particularly suitable for small water turbines and small and medium-size water pumps.

Some of the hydropower stations in China have water diversion as one of their functions. In building this type of power station, it is also necessary to build a pressure adjustment well in order that the safety of the generating unit and the tunnel can be ensured. This will cost a lot of money and material. The Xian Heat Treatment Research Institute of Shaanxi Province, the Yangzhou Power Equipment Repair and Manufacturing Plant of Jiangsu, and the Huadong Power Design Institute invented the equipment for the hydraulic interlocking control of TFW-400 Model Pressure adjustment valve. The building of the pressure adjustment well will not be necessary if this equipment is installed in the power station.

Metallurgic Industry

[Article by Xu Yaozhong [1776 5069 0022]]

General Description

In 1979, the steel output of the metallurgic industry in China reached 34.48 million tons, the world's No 5, and an increase of 8.5 percent over that of the previous year. Its output of pig iron was 36.73 million tons, a 5.6 percent increase over that of the previous year; and the output of rolled steel was 24.97 million tons, a 13.1 percent increase over that of the previous year. Thus the increase of rolled steel output was more than that of steel, and the increase of steel output was more than that of pig-iron. This is a gratifying result. The output of nonferrous metal exceeded 1 million tons, a 12.9 percent increase over that of 1978.

The quantity of metallurgic products surpassed the best in history. There were 101 iron and steel products rated as fine-quality products, and 15 varieties of them won state gold or silver medals for their fine quality. In the same year, the metallurgical system successfully trial produced 9,000 new varieties and new materials, and carried out 301 successful scientific experiments. The varieties of rolled steel has been increased, and the varieties in short supply were increased by 2.86 million tons to meet the requirements of agriculture and light industry.

In 1979, energy consumption in metallurgic industry was decreased markedly as compared with 1978, and the energy saved was equivalent to more than 4 million tons of standard coal. The key metallurgic enterprises earned more than 5.85 billion yuan in profits.

Before liberation, the foundation of this industry in China was very weak. In 1949, it produced only 158,000 tons of steel. In 1957, the output was increased to 5.35 million tons. It was over 10 million tons in 1959; over 20 million tons in 1971; and over 30 million tons in 1978. In 1979, the metallurgic industry continued to develop for the third year after the smashing of the "gang of four." The output then was 215 times that of the early post-liberation period, and topped all previous records.

In China, there are now about 2,000 metallurgic enterprises owned by the whole people, with some 4.1 million workers and staff members. It is capable of producing more than 20,000 types of steel products and have initially become a complete metallurgic industrial system with different departments serving different functions. Among the main iron and steel producing centers in China are the Anshan Iron and Steel Company, the Benxi Iron and Steel Company, the Shoudu Iron and Steel Company, the Baotou Iron and Steel Company, the Maanshan Iron and Steel Company, the Panzhihua Iron and Steel Company, the Chongqing Iron and Steel Company, the Shanghai Metallurgy Bureau, and the Tianjin Metallurgy Bureau. Among the production bases of nonferrous metal are Baiyin, Daye, Zhongtiaoshan, Dongquan, and Tongling.

New No 2 Blast Furance of Shoudu in Operation

The first blast furnace of fairly advanced technology in China--the New No 2 Blast Furance of Shoudu Iron and Steel Company--has a capacity of 1,326 cubic meters, and was designed, manufactured and equipped in China. It is a top-burning type with a "material-less bell" [2477 2435 6988] top, using high temperature blast air. It also has a conveyor belt system for feeding materials, and has the advanced technological features of automatic sampling, temperature checking, analyzing, and so forth.

Construction of this blast furnace began by the end of 1977, and operation was started in late December 1979. The operation has been quite normal and productivity greatly raised. From 1 to 25 March 1980, the utilization coefficient of this blast furnace reached 1,729 ton/cubic meter day and night, and the coke ratio was 525 kilograms, being of the advanced national level.

Coefficient of Blast Furance Utilization in Shoudu Iron and Steel Company Reaches Advanced World Level

The Shoudu Iron and Steel Company has four blast furances with a total capacity of 3,561 cubic meters, the smallest one being 576 cubic meters and the largest one being 1,200 cubic meters. The equipment used belonged to the 1950's and 19[illegible]0's. In recent years, the plant strengthened its management and made rapid progress. In 1979, the annual average furnace utilization coefficient was 2,094 ton/cubic meter day and night, and the coke ratio was 433 kilograms/ton. The No 1 Blast Furance in September had an average monthly utilization coefficient of 3,114 ton/-cubic meter day and night, and the coke ratio was 362 kilometer/ton. All these were new records.

This plant has the highest average utilization coefficient and highest single furance utilization coefficient among all Chinese iron smelting plants. It is also among the advanced world level.

Commissioning of 1.7-Meter Rolling Mill in Wuhan Iron and Steel Company

In 1979, when the Wuhan Iron and Steel Company had put its 1.7-Meter Rolling Mill into operation, its annual output was 220,000 tons of continuous cast steel billets, 298,000 tons of hot-rolled plate steel, and tin- and zinc-plated sheets; 148,000 tons of cold-rolled sheet steel; and 20,000 tons of cold-rolled silicon steel. The quality of all these products was up to the designed standard. The operation of this equipment is of great significance in ending China's backwardness in steel-rolling and in increasing the varieties of steel materials.

The 1.7-Meter Rolling Mill project of Wuhan Iron and Steel Company was a large-scale imported project. It has five components, namely the No 2 steel-smelting plant, the continuous casting workshop, the hot-rolling plant, the cold-rolling plant, and the silicon sheet steel plant. Except for the No 2 steel-smelting plant which was designed and constructed in China, the equipment for the other three plants and one workshop was all imported. The continuous casting and the cold-rolling equipment was imported from Japan. The whole set of equipment was supplied from more than 200 foreign trading firms. This equipment has the features of being large and automatic in addition to its high speed and continuous operation. The new technology used belongs to the advanced level of the 1970's. Its capacity is 3 million tons of hot-rolled sheet and plate steel, which can be processed into 2.79 million tons of finished products.

This project was carried out during the struggle against the interference and sabotage by the "gang of four." From the formal beginning of the construction in June 1975 up to its basic completion in December 1978, the entire process took 42 months. Then trial production began in the last quarter of 1978.

[Article by Guo Changxi [6753 2490 3588]]

Construction of Modern Baoshan Iron and Steel Complex

Baoshan Iron and Steel Complex, a modern iron and steel complex of China, is located along the Changjiang River bank in Yuepu Township of Baoshan County, Shanghai, and occupies an area of about 11 square kilometers. This is a gigantic imported project approved by the Party Central Committee and the State Council. After completion, this complex will have a wharf capable of accommodating 50,000-ton vessels carrying in raw materials, and workshops for coking, sintering, iron smelting, preliminary rolling, seamless steel pipe making, continuous cold rolling, continuous hot rolling, and its own power generation plant.

The completed Baoshan Iron and Steel Complex will have large-scale operation, new technology and high efficiency as its special features. Its designed capacity is the output of 6.5 million tons of iron and 6.7 million tons of steel each year. Its principal items of equipment will include two blast furnaces with a capacity of 4,063 cubic meters, three 300-ton top-blown oxygen converters; two sets of continuous plate casting machines, four large coking ovens, two 450-square meter sintering machines and a system of steel-rolling. The entire project is expected to be completed and put into operation by the end of 1984. By that time, there will be a bigger increase of steel products in Shanghai, and the proportion of steel plates, steel pipes and fine-quality steel in its steel materials will be doubled. The various economic targets of Shanghai steel industry will attain advanced world level. This will obviate the need, which has long been in existence, for China to spend huge sums of foreign exchange in importing steel.

According to the overall arrangement, the Shin Nippon Seitetsu Kaisha was responsible for the design while China was to undertake the construction for the design while China was to undertake the construction of the complex. Since it is located in the Changjiang Delta, an alluvial plain, over 10,000 steel-tube, concrete and sand piles had to be driven into the ground to consolidate the foundation. Workers from various parts of the country were organized by Shanghai Municipality and the Ministry of Metallurgic Industry to fight a mass battle. By the end of December 1979, more than 3,700-steel-tube concrete and sand piles had been driven into the ground to prepare the foundation for the blast furnace, converters, coke ovens and power plants. The wharfs built along the banks of Changjiang River for the working ships, for the transportation of sand and stone materials and large sets o equipment had also been completed and put into operation, while work on the ground surface for the building of power plants, steel-smelting and repair plants had already begun. The construction has made rapid progress since it was formally begun on 23 December 1978, and the quality of work has received favorable comments from the departments concerned.

Popularization of New Technique of "Grinding after Sieving" in Ore Selection

China has rich resources of low-grade [magnetic] iron ore. The new ore selection technique of "grinding after sieving" was first successfully used by the Dagushan Iron Mine of Anshan Iron and Steel Company. Through this technique, "pure" minerals can be obtained through its separation from other elements and high grade ores are obtained. Ores with more than 30 percent of iron can thus be upgraded to those of 67-68 percent. This new technique is of great economic value, and was popularized throughout the country in 1979. The ores selected by the key factories may contain more than 65 percent of iron while those selected by ore-selection plants of Shoudu Iron and Steel Company and the Nanfen Selection Plant of Benxi Iron and Steel Company were more than 68 percent, which is an advanced world level.

Machinery Industry

[Article by Huang Fenchu [7806 1144 0443]]

China's Machinery Industry with a Basically Complete Assortment

China's machinery industry has now become a basically complete system with different functions of a fairly wide scope and high technical level. These departments have played an important role in promoting agriculture, industry, national defense, science and technology.

In the early post-liberation period, there were only very little processing equipment, and whatever machinery China had were concentrated in Shanghai, Tianjin and Shenyang, for repairing, assembling, or producing a small number of motors, small water pumps, belt-driven lathes and other simple items. Now China's machine building capacity has been greatly expanded, and in the industrial system of the First Ministry of Machine Building alone, there are nearly 100 machine building trades of different sizes, and their products include automobiles, mine excavators, meters and instruments, and so forth, totaling more than 26,000 varieties. They are even capable of supplying complete sets of equipment for agriculture, industry, communications and transportation, national defense, scientific research and other departments. These complete sets of equipment include those required by iron and steel complexes with an annual output of 1.5 million tons of steel, complete sets for coal mines with an annual output of 2.5 million tons of coal; equipment for large oil refineries treating 2.5 million tons of crude oil a year; large hydropower generating units generating some 300,000 kilowatts; equipment for producing 300,000 tons of synthetic ammonia and 240,000 tons of urea a year; equipment for transmitting and transforming 330,000 volt electricity; large and long oil pipelines, and so forth. In 20 years from 1959 to 1979, these departments also produced complete sets of equipment for large construction projects.

China's machinery industry is capable of not only supplying complete sets of equipment but also developing high-grade precision advanced products which are beginning to approach or surpass the advanced world levels. China is now able to produce more than 80 different types of high-precision lathes required for producing high precision spare parts, and the annual output is more than 2,000 sets. It is no longer necessary for China to rely entirely on imported high-precision machines. The new instrument and meter industry has also rapidly developed in recent years. Some high-precision instruments and automatic meters are being produced, and some of them, such as the high precision electric bridge, potential difference gauge, standard resistance, and 60-line electro-magnetic oscilloscope have approached advanced world level.

Along with the rapid development of the machinery industry, the sale of Chinese products has been expanded to 111 countries and regions, and 114 types of exported products including lathes, forging equipment, automobiles, electric motors, ball-bearings, measuring and cutting tools, instruments and meters, are all well-received by the customers.

General Description of Production and Construction under the First Ministry of Machine Building

While implementing the policy of readjustment, restructuring, consolidation and improvement of the national economy, all departments under the First Ministry of Machine Building have adopted measures to boost production with certain success. In 1979, the capacity of generating equipment was up to 6 million kilowatts, an increase of 33.3 percent over the previous year; the number of lathes produced was 95,100, a 3.5 percent reduction below that of the previous year; and the number of automobiles produced was 167,800, a 25.4 percent increase. The total output value by the departments under the First Ministry of Machine Building was 36.07 billion yuan, an 11 percent increase over that of the previous year. Each worker created an output value of 11,000 yuan, 600 more than that of 1975 when labor productivity was already high. Many enterprises have improved their business management, strengthened their economic accounting, and strived to increase both production and income. The total profits for 1979 was 6,000,310,000 yuan, a 9.8 percent increase over that of 1978. The circulating capital required to produce every 100 yuan of output value dropped by 9 percent, and the output value produced by every 100 yuan of fixed assets rose by 7 percent over the previous year.

New improvement was noted in the quality of products. The machinery enterprises in various localities earnestly consolidated their own resources and launched the "trustworthy" campaign, besides producing brand-name products and catching up with or surpassing the advanced level. As a result, the products of various provinces, municipalities and autonomous regions, according to the result of a strict quality check, were 97.4 percent up to the required standard. The varieties of products were also increased and more than 900 new varieties were produced in 1979.

Consumption of raw materials and energy was reduced. The utilization rate of steel products was increased by 3.3 percent over that of 1978; and coke consumption for each ton of metal out of the copula furnace was reduced by 7.3 kilograms; and power consumption for each ton of steel out of electric furances was reduced by 32.4 kwh below that of 1978.

Investments in capital construction produced fairly good results. Two construction projects, namely the Hangzhou Brake Material Plant and the Leihe warehouse of Henan were completed and already in operation. So too were three single item construction projects including the High-Speed Gear Box Factory of Nanjing. The newly increased value of fixed assets in 1979 totalled 740 million yuan which was equivalent to 93.7 percent of the total investments for the same year. The productive capacity of friction materials was increased by 500 tons; that of heavy-duty cross-country vans, by 100; that of heavy-duty gear-boxes, 20 sets; that of power station boilers, 808 ton/hours; that of water treatment equipment, 2,370 tons; and that of power generating equipment, 100,000 kilowatts. These projects will play an active role in expanding the production of machinery and power products.

Key Enterprises under First Ministry of Machine Building Consolidated

Outstanding results have been achieved in the consolidation of key enterprises under the First Ministry of Machine Building. After the consolidation, more than 50 percent of the 655 key enterprises are up to the required standard according to the 12 Articles of Consolidation. More than 90 percent of the key enterprises under No 1 Machinery and Power Bureau of Shanghai, the Machinery Bureau of Beijing, No 1 and No 2 Machinery and Power Bureaus of Tianjin, and No 1 Machinery and Power Bureau of Heilongjiang Province are all up to the standard.

The consolidation of these enterprises began in 1977, when the First Ministry of Machine Building issued the 12 Articles calling for: effective quality control; strict technical control; better equipment control and maintenance; careful handling of technical equipment; improved product design; balanced production, "civilized" production and safe production; reduced consumption and increased accumulation; fruitful technical training, and so forth.

Since the consolidation, the advanced enterprises have further improved their management while some enterprises with "longstanding, big and difficult" problems have taken on a new complexion. As a whole, the success of enterprise consolidation is mainly manifested in the general improvement of the quality of products. Before the consolidation, about half of the products of the key enterprises were substandard. Now, according to a spot check conducted by the Ministry on 83 varieties of key products, 98 percent of them were up to standard. By the end of 1979, the machinery bureaus of 16 provinces and municipalities conducted strict examinations on 864 varieties of products, among which 240 varieties were found to be of first class quality, and 583 varieties were up to standard. A total of 109 varieties were named by the Ministry as "trustworthy quality" products, and another 12 were given state quality awards.

The success of consolidation among these key enterprises was further shown in the change from losses to profits. In 1976, 67, or 10.2 percent, of these enterprises suffered losses to the amount of 172 million yuan. After the consolidation in 1979, only 4 key enterprises suffered losses and the amount of losses was reduced to 6.9 million yuan.

Largest Low Water Head Water Turbine Generating Unit Completed

The first low water head propeller type water turbine power generating set, designed and manufactured in China to be used on the power station of Gezhouba in the multiple-purpose water conservancy project on the Changjiang River was completed by the Dongfang Power Machinery Plant in Suchuan on 30 November 1979.

The generation of hydropower requires different water turbine generators according to different water heads. This generating unit, specially designed and manufactured for the Gezhouba Power Station is a rotary structure with four propeller blades attached. This type of turbine was first manufactured in China. With a capacity of 170,000 kilowatts, this unit is 30 meters high and the diameter of the rotor is 11.3 meters with four stainless steel blades attached. These blades are not only heavy and bulky, but also very complex in shape with very many different thicknesses. The required work process is very intricate. The stainless steel for the blades is a new type produced in China after careful research. It is very strong, tough and corrosion resistant. The turbine produces great pressure, and, under a water head of 18.6 meters, the designed flow is 1,130 cubic meters per second.

The research on and manufacture of this low water head generating unit were possible because of the strong supports from more than 30 scientific research units, institutions of higher learning and the factories concerned. Parts of this unit are being gradually transported to the construction site in Gezhouba for installation in the power station.

Successful Trial Operation of Large Synthetic Ammonia-Making Equipment in Shanghai

China has designed and manufactured its first set of equipment for producing 300,000 tons of synthetic ammonia and 240,000 tons of urea annually--a piece of equipment of the advanced 1970's level. On 31 December 1979, a successful trial operation of this equipment was carried out in Wuming Chemical Industry Plant of Shanghai. The Grade One synthetic ammonia and the urea particles containing ammonia were above the national standard.

This gigantic set of equipment consists of more than 700 separate parts and more than 10,000 valves and meters. It was jointly designed and manufactured by more than 400 units in different parts of China. It is capable of producing 300,000 tons of synthetic ammonia and 240,000 tons of urea, and symbolizes a big step forward taken by China in the machinery and power, metallurgy, instruments and meters, and chemical industries, besides an accumulation of new experiences in the domestic production of large chemical fertilizer equipment.

Special Technology Exported to West Germany

In 1979, the Hangzhou Oxygen-Making Machinery Plant of China sold to a firm of the Federal Republic of Germany the special technology of manufacturing heat converters of the wing type. The first batch of technical data has already been delivered according to the agreement. This is the first time for China to transfer its patent technology to a foreign country in the machinery industry.

According to the agreement signed in July 1979 between the China National Machinery and Equipment Import and Export Corporation and Linde Company of West Germany, the Chinese plant will sell to the German firm the complete data for the manufacturing of the wing-type heat converters together with the accessory equipment for molding the wings including four sets of special equipment and six sets of molds, all to be delivered within 10 years. The Hangzhou Oxygen-Making Plant will send specialists to the German firm to assist in the installation and adjustment of the equipment, and also undertake to train people sent to the plant by the German firm.

Heat converter is an important component of the oxygen-making machinery. The wing-type heat converters produced by the Hangzhou Oxygen-Making Machinery Plant are of fine quality, low production cost, and fairly advanced technology. The German customer was interested particularly in the unique feature of the wings.

Linde Company of West Germany is one of the leading oxygen manufacturing firms in the world, and the Hangzhou Oxygen-Making Machinery Plant is the largest of its kind in China. These two enterprises also signed an agreement on cooperation in manufacturing 10,000 cubic meter and 28,000 cubic meter oxygen-manufacturing machines.

Technical Demonstrations and Exchange of Experiences in Machinery Industry

More than 400 skilled workers of the machinery industry arrived in Shanghai on 10 September 1979 to give technical demonstrations and exchange experiences in a 10-day seminar sponsored by the All-China Federation of Trade Unions, the Chinese Science and Technology Association, the First Ministry of Machine Building, and the Ministry of Agricultural Machine-Building Industry. This is the largest gathering of its kind in China since liberation.

Representatives from various localities gave skillful demonstrations and exchanged experiences in 309 advanced techniques of metal cutting, casting, welding, heat treatment, and press forging. The exchange and popularization of advanced techniques have given a strong impetus to the tapping of potentials and renovation and transformation of equipment in the machinery industry throughout the country. Ni Zhifu [0242 1807 4395], Political Bureau member of the Party Central Committee and Chairman of the All-China Federation of Trade Unions; Wang Chonglun [3769 1504 0243], model-worker of national fame and Vice Chairman of All-China Federation of Trade Unions; and responsible persons of the Shanghai CCP Committee and the departments concerned, attended this gathering. There were also many famous veteran model workers and fine young workers, and technicians. Worker-turned-engineer Sun Maosong [1327 5399 2647], known as the "miraculous handler of knives" of the Harbin Oxygen-Manufacturing Plant, gave a demonstration of high-speed "picking of worms" [tiao wogan; 2176 3260 2616], while worker Gu Zhi'an [6328 1807 1344] of the Yongding Machinery Plant of Beijing, demonstrated his skill in drilling. After Gu Zhi'an, Ni Zhifu also gave a similar demonstration. Young worker Yang Chenhuai [2799 6591 2037], the champion in a welding contest held in Shanghai, also gave a demonstration of his skill in copper welding. Their fine performances won great applause from the audience.

Construction Materials Industry

[Article by Zhou Zhong [0719 1813]]

General Description

The construction materials industry in China has undergone very great development in the 30 years after the founding of the People's Republic. There are now more than 46,000 construction material enterprises with more than 3.5 million workers and staff members in the country. Among them, some 5,000 are owned by the whole people with more than 1.4 million workers and staff members; and some 40,000 are owned by the collectives, with some 200,000 workers and staff members. In 1979, the total output value of construction materials in the country was 16.7 billion yuan.

There have been big increases in the varieties of products in the construction materials industry. There are now three large categories of products controlled by different departments of the Ministry of Construction Materials:

First, materials used in civil engineering. The main items are cement, plate glass, ceramics for bathrooms, asphalt felt, bricks, tiles, sands and the items newly developed in the past 10 years including aerated concrete, gypsum boards, asbestos and cement plates, steel mesh cement plates, plastic wall papers, fiber glass wall papers and various types of blocks.

Second, the nonmetallic mineral products. Among them are limestones, quartz stones, Dali stones, granites, gypsum, porcelain clay and so forth. Some of them are construction materials and others are used as raw materials for the same purpose.

Third, new inorganic nonmetallic materials or finished products processed mainly from raw materials of the above two categories. They are glass fibers, graphite fibers, reinforced plastics, industrial technological glass, quartz glass, special ceramics, cast stone, cement pressure pipes, cement boats, cement railroad sleepers, cement power poles and so forth.

The output and varieties of various construction materials were increased. In 1979, the national cement output was 73.9 million tons, an increase of 13.3 percent over that of 1978. The varieties of cement was increased from just a few before liberation to nearly 100. In addition to ordinary cement of different labels and slag cement, there are now special cements for dams and oil wells, quick-setting, quick-hardening and high-strength cements for emergency use, expanding cements, and colored cements. In 1979, the national output of plate glass was 23.3 million standard crates, an increase of 16.3 percent over that of 1978. In addition to plate glass of various thicknesses for different construction purposes, there were also reinforced curved plate glass, polished glass, laminater glass, glass with embossed designs, and endothermic glass, all extensively used in the electronic, automobile, aviation, chemical and instrument and meter departments. In the past, there was only one variety of ceramics for bathrooms; now there are more than 20 varieties, including glazed bricks and wall and floor bricks. The varieties are constantly increasing and the quality continues to improve.

Despite these developments, the construction materials industry is still a weak link in our national economy. At present, the quantity and varieties of most products are not keeping up with the needs, and that is why the construction materials industry departments must advance and develop in the process of readjustment in order to pave the way for laying a good foundation, and become the vanguard preparing still greater for national economic development following the readjustment.

Development of Cement Industry

China produced 73.9 million tons of cement in 1978, an increase of 13.3 percent over that of 1978. There are now 49 large and medium-size cement enterprises in operation. They have a total of 133 cement kilns, capable of producing 17 million tons of clinkers, and 210 cement grinders with a productive capacity of 27 million tons. In 1979, these cement plants produced a total of 24.72 million tons of cement, an 11.1 percent increase over that of 1978. More than 10 large and medium-size enterprises are under construction. Among them are Huaihai, Jidong and Ningguo plants which will use the new equipment of advanced world level that permits "decomposition outside the kiln."

There are more than 5,700 small cement factories in China. About 2,400 of them are owned by the whole people while some 3,300 are run by the communes and production brigades under the collective ownership system. According to incomplete statistics, these small factories produced a total of 47.73 tons of cement, a 12.2 percent increase over that of 1978. The building of these small cement factories was financed with locally raised funds under the spirit of self-reliance and hard struggle. They are growing along with the development of farmland capital construction and have made important contributions to the development of local industry and the increase of the economic power of the people's communes. In 1979, these small cement factories actively implemented the policy of "readjustment, restructuring, consolidation and improvement" by raising the quality of products, lowering the production costs and improving their management.

New Construction Materials

For hundreds of thousands of years, China mainly used bricks and tiles made of clay as materials for building houses. Along with the advance of science and technology, these materials are no longer adequate for China's large-scale economic construction and the improvement of people's housing requirements. Since the 1960's, China has carried out research on new materials to be used as the walls and the roofings, and established a number of experimental plants. Since 1975, there have been big developments in China's output of light frame-and-panel building materials, based on advanced foreign technology and better use of the country's natural resources. Other new building materials are: prefabricated reinforced concrete beams, plates, columns and pillars, to be used for the framework; gypsum board, aerated concrete, asbestos cement plates and reinforced concrete slabs to be used for the interior and exterior walls; mineral wool felt and plates to be used for sound and heat insulation; glass fiber felt, water-proof cement and "caulking oil tubes" to be used as water-proof materials for the roofings and exterior walls; and patterned and colored plastic wallpapers and glass fiber wall coverings to be used for decorating the interior walls. With these materials in addition to windows, finishing hardware, water, electrical and heating systems and toilet fixtures, we will be able to build integral houses which are not so heavy. With these new materials, again, experimental houses with a total floor space of more than 200,000 square meters were built in 1979. Displaying the spirit of self-reliance and hard struggle, Suzhou Municipality has remodelled and expanded the old construction material enterprises, and in slightly more than 1 year, set up a base capable of producing enough materials for 100,000 square meters of housing. Some 80,000 square meters of residential houses were then built. At present, Beijing is setting up a large new base, consisting mainly of imported production lines supplemented by local auxiliary equipment, to produce materials for 1 million square meters of housing. In Harbin, Wuhan and Shenyang, medium-size bases, capable of producing materials for 500,000-800,000 square meters of housing, are being established. Suzhou Municipality is also expanding a base producing materials for 200,000 square meters of housing, and Shijiazhuang is also building up a base of similar size. Wuxi Municipality is planning to build one with a capacity of 100,000 square meters.

Utilization of Wastes

One method to develop the production of construction materials is to utilize various types of industrial slag and other wastes, such as coal stones, coal ashes, and metal and furance slags as raw materials. Since the founding of the People's Republic, many research organs and processing factories have continued their study on the use of slags and waste materials. Now, the following items are being produced as a result of successful experiments: bricks and blocks made of coal ashes; aerated concrete and ceramic particles made of coal ashes; and bricks, tiles and blocks made of gangue instead of clay. Lime and other slag from the furnaces are also mixed with cement to produce concrete. Large quantities of mixed materials made of furnace slags are being used. At present, approximately 300 million tons of industrial slag are discharged every year, and approximately 30 million or 40 million tons of them are used for making construction materials. In 1979, the construction material industry departments are making comprehensive use of more than 10 million tons of gangue. If this amount of gangue is used for heating, we can save 2 million tons of coal. Full utilization of these wastes will not only help us economize, but also promote the welfare of people by eliminating environmental pollution.

Chemical Industry

[Article by Li Niangui [2621 1628 6311]]

General Description

China's chemical industry has developed rapidly. By the end of 1979, there were 7,362 large, small and medium-size chemical enterprises in China, including 302 key enterprises and 4,744 others owned by the whole people. The number of their workers and staff members was some 2.8 million.

In 1979, on the basis of summing up the practical experience in China's chemical industry, the Ministry of Chemical Industry formulated the production policy of "supporting others to develop ourselves" in an effort to serve agriculture, light and textile industries and the market by increasing the production of goods in demand and at the same time to develop the chemical industry itself. In the same year, the total output value of the chemical industrial system was 57.4 billion yuan, a 9.4 percent increase over that of 1978, and the profits handed over to the state increased by 11 percent over that of the previous year. State plans for 19 varieties of products were all fulfilled, and the plans for 14 of them were fulfilled 1 month ahead of schedule. The total national output of chemical fertilizer was 10.65 million tons, an increase of 22.6 percent; that of chemical insecticide was 587,000 tons, an increase of 0.8 percent; and those of caustic soda and soda ash, which were in short supply, were increased by 11.3 percent and 11.8 percent respectively, entirely through tapping the potentials of the old plants. The outputs of synthetic ammonia, calcium carbide, pure benzene, ethylene, paint, processed rubber and so forth were increased by 10 percent to 24 percent. The output of processed crude oil by the five large oil refineries was increased by 10.8 percent over that of the previous year.

Consumption of fuel, power and raw materials in the chemical industry was decreased by a wide margin in 1979, and outstanding success was achieved in energy conservation. The consumption index of the 10 key items designated by the state was lowered by 1-6 percent, and in the same year, 3.9 million tons of coke, 1.6 billion kwh of electricity, and 70,000 tons of oil were saved.

Readjustment in the Ministry of Chemical Industry began to show effects in 1979. Some enterprises having high consumption of fuel and raw materials, producing goods of inferior quality, and sustaining losses over a long time had to be suspended for consolidation; some 440 small factories and mines were closed, suspended, merged with others or converted to other lines of production; and 39 large and medium-size projects were either halted or put off for the time being. Thanks to the concentration of resources, 38 single item projects were completed and commissioned in 1979 despite a reduction of investments.

The Newly Emerging Petrochemical Industry

China's petrochemical industry developed rapidly in the past 10 years as a new industry. By 1979, there were 28 key enterprises engaged in petrochemical industry, including the Yanshan General Petrochemical Company of Beijing, the Lanzhou Chemical Industry Company, the Shengli General Petrochemical Industry Plant of Shandong, the Yueyang General Chemical Plant, the Anqing General Petrochemical Plant, and the Guangzhou Petrochemical Industry Plant. In 1979, the output of ethylene was 435,000 tons; plastics, 793,000 tons; synthetic rubber, 120,000 tons; and synthetic fiber materials (including those of the textile departments), 200,000 tons. These outputs exceeded those of 1969 by 10 to several tens of times.

China's petrochemical industry began in the late 1950's. The first petrochemical industry enterprise--the Synthetic Rubber Plant of Lanzhou Chemical Industry Company--was founded in 1958 and commissioned in 1971. This was followed by the Dalian Organic Chemical Industry Plant with an annual output of 15 million tons of ethylene, and the Gaoqiao Chemical Industry Plant of Shanghai with an annual output of 67 million tons of ethylene, and several small petrochemical industry plants in Jiangsu, Liaoning and Jilin.

While speeding up the building of small petrochemical plants, a set of sand cracking equipment with an annual output of 36,000 tons of ethylene was imported from abroad in 1964. Then in 1973, another large equipment with an annual output of 30,000 tons of ethylene was imported. Throughout the 1970's, a total of 32 sets of petrochemical industrial equipment were imported, and these sets, combined with those designed, manufactured or built in China have contributed to the large-scale development of the petrochemical industry in China.

Petrochemical industrial products can not only meet the requirements in many fields, but also bring high profits to help the state accumulate more funds because of its high output value. In 1979, for example, the Yanshan General Petrochemical Plant processed 5.86 million tons of crude oil, and produced 1.74 million tons of gasoline, diesel oil, kerosene and lubricating oil, 227,000 tons of ethylene, 161,000 tons of polyethylene from high pressure process, and 41,000 tons of butadiene rubber, with a total industrial output value of 2.5 billion yuan and profits and taxes for the state totaling 1 billion yuan. In the same year, the Shengli General Petrochemical Industry Plant's total output value was 1,296 million yuan, with a total of 530 million yuan of profits and taxes.

Thirteen Sets of Large Chemical Fertilizer Equipment in Operation

During the Fourth Five-year Plan, China imported 13 sets of large chemical fertilizer equipment with a daily output of 1,000 tons of synthetic ammonia and 1,620 tons of urea. These sets have all been in operation since September 1979.

These 13 sets of chemical fertilizer equipment were manufactured with new technology of the 1970's, and their productive capacity amounts to one-fifth of the total national output of synthetic ammonia. The large backbone enterprises with modern equipment, the 1,400 small and 50 medium-size nitrogenous fertilizer plants, have combined to form a nitrogenous fertilizer production network.

The 13 sets of chemical fertilizer equipment were separately installed in Sichuan Chemical Plant, Luzhou Natural Gas Chemical Plant, Yunnan Natural Gas Chemical Plant, Chishui Natural Gas and Chemical Fertilizer Plant of Guizhou, Daqing Chemical Fertilizer Plant, Liaohe Chemical Fertilizer Plant of Liaoning, Cangzhou Chemical Fertilizer Plant of Hebei, Chemical Fertilizer Plant No 2 of the Shengli General Petrochemical Plant of Shandong, Nanjing Qixiashan Chemical Fertilizer Plant of Jiangsu, Anqing General Petrochemical Plant of Anhui, Dongting Nitrogenous Fertilizer Plant of Hunan, Hubei Provincial Chemical Fertilizer Plant, and Guangzhou General Petrochemical Plant. With the exception of three sets which still have some problems, all the rest are of a high technological level and are quite dependable. They can utilize heat energy comprehensively and produce remarkable economic results. The main economic targets are up to, or close to, the same level of similar plants abroad. The annual output of synthetic ammonia of Sichuan Chemical Plant, Luzhou Natural Gas Chemical Plant, Yunnan Natural Gas Chemical Plant, Chemical Fertilizer Plant No 2 of the Shengli General Petrochemical Plant of Shandong, Daqing Chemical Fertilizer Plant, and Cangzhou Chemical Fertilizer Plant in 1979 was all more than 300,000 tons. According to statistics, the average energy consumption of these 13 sets of equipment for producing each ton of synthetic ammonia is 1,000 kilocalorie, and the production cost is relatively low.

Rapid Development of Small Nitrogenous Fertilizer Industry

China's small nitrogenous fertilizer industry has developed very rapidly and become a new force in China's chemical fertilizer industry. By the end of 1979, there were 1,452 small nitrogenous fertilizer plants in China, and more than 200 of them had annual output of more than 10,000 tons. Their total output of synthetic ammonia in 1979 was 7.31 million tons, or 55 percent of the total national output. The output of Zhejiang, Jiangsu, and Sichuan was more than 20 percent over that of 1978.

Because of the effective measures for reducing consumption, the average coal consumption for each ton of synthetic ammonia by these small plants was reduced from 3,257 kilograms to 2,750 kilograms, and power consumption was reduced from 1,765 units to 1,594 units. The production cost for each ton of synthetic ammonia was 450 yuan. In the whole country, 399 small nitrogenous plants made profits, and 37 of them earned more than 1 million yuan each. Taking both profits and losses and state subsidies into account, there was basically no deficit. The quality of products from these small plants have also improved, and the quality of carbonate ammonia and ammonian fluid produced by 22 provinces, municipalities and autonomous regions was 95 percent up to the standard. In 12 provinces, municipalities and autonomous regions, more than 80 percent of their products was rated as first class goods.

Small nitrogenous fertilizer industry began in 1958 in China. The Chinese method of production is unique. Because of the development of the small nitrogenous fertilizer industry, the amount of chemical fertilizer applied to each mu of farmland in China was 29.3 kilograms in 1978. Fertilizer application was further increased in 1979.

Fine-Quality Chemical Products

Fine-quality chemical products in China were greatly increased in 1979. In a national quality evaluation, 17 types of products were honored with the award of national gold and silver medals, and 237 others were rated as fine-quality products.

The fine quality of "Red Triangle" soda ash produced by Tianjin Soda Plant was up to the advanced world level. It is well-known at home and abroad for its purity and transparency after melting. It can be exported without further examination. The Gonglian Brand industrial ammonia bicarbonate of Dalian Chemical Plant is selling well at home and abroad. The Yanshan Brand butadiene rubber produced by Yanshan General Petrochemical Plant of Beijing has the fine quality of being elastic, wear-resistant and cold-resistant in addition to its bending strength and durability, and is extensively used in the production of tires, rubber belts, rubber hoses and other rubber products by more than 300 factories in the country. In 1979, it was put on trial sale broad, and was highly commended by foreign traders. The Youyi Brand 729 "inwardly pimpled" rubber paddles produced by Tianjin Rubber Research Institute have high elasticity and a high coefficient of friction with the ball. These five products won gold medals from the state.

The Beijing Brand chemical reagent, produced by Beijing Chemical Plant, is a fine quality chemical product prepared with meticulous care, to be used in scientific research and for analysis and tests in industrial and agricultural production, medical treatment and public health, culture and education, and various trades and professions, serving as a means of measurement and weighing. In the opinion of users, it is dependable, efficient and of good quality, and thus enjoys a good reputation at home and abroad. This product has had a history of more than 20 years and been exported to more than 20 countries and regions for more than 10 years. It is well received abroad because of its fine quality. The Tiangong Brand caustic soda produced by Tianjin Chemical Plant enjoys good reputation because of its high purity and fresh color, and is meeting a big demand in the home market. The solid caustic soda produced with the use of mercury has all along surpassed the national standard for first-class goods and well received by consumers at home as well as in Hong Kong, Macao, and the Southeast Asian regions. Both products won silver medals from the state.

The Three-Six-Nine Contest Organized by Ministry of Chemical Industry

In 1979, the Ministry of Chemical Industry organized a contest among three municipalities, six provinces and nine large enterprises (briefly referred to as "Three-Six-Nine" Contest), as an impetus to the campaign to increase production and practice economy. Among the participants of this contest were from the three municipalities of Beijing, Tianjin and Shanghai; the six provinces of Hebei, Shandong, Henan, Sichuan, Jiangsu and Hunan; and nine large enterprises, namely, the Jiling Chemical Company, the Lanzhou Chemical Company, the Nanjing Chemical Company, the Yanshan General Petrochemical Company of Beijing, the Shengli General Petrochemical Plant of Shandong, the Yueyang General Chemical Plant, the Quzhou Chemical Plant, the Dalian Chemical Plant and the Jinzhou Chemical Plant. The results of the contest were as follows: Beijing Municipal Chemical Industry Bureau was the champion among the three municipalities; Jiangsu was the champion of the six provinces; and Yueyang General Chemical Plant was the champion of the nine large enterprises. In the second half of 1979, the scope of the contest was expanded to include 10 municipalities affiliated with the provinces, namely, Chongqing, Wuhan, Nanjing, Shenyang, Guangzhou, Qingdao, Luda, Xian and Harbin. The total chemical output of these three municipalities, six provinces, nine large enterprises and, together with the 10 province-affiliated municipalities, accounted for 72 percent of the total national chemical output, and their profits accounted for 86 percent of the total national profits. Improvement of these provinces, municipalities and enterprises means effective control of the key links and the improvement of the entire chemical industry.

The participants of the contest upheld the principle of "putting learning, helping and encouragement first and competition second." During the contest, they kept one another informed of their conditions of production, exchanged their advanced experiences and publicized their economic information. The surplus and shortage of materials among them were adjusted and some municipalities even helped promote the sale of one another's goods. This contest greatly helped some provinces and municipalities formerly having a weak foundation. For example, the output value and profit level of Xian Municipality before the contest were lower than those of the same period in 1978. After learning from the experiences of Changzhou, Chongqing and Wuhan, and by November, it began to catch up, and its output and profit level increased by 2.5 percent and 11 percent respectively over those of the same period in 1978.

Inspired by the "Three-Six-Nine" Contest, Sichuan, Jiangsu and other provinces have also held contests among their own municipalities, prefectures, trades and enterprises. These contests have played an important role in the fulfillment or overfulfillment of the chemical production tasks for 1979.

Textile Industry

[Article by Li Anding [2621 1344 1353]]

General Description

China originally had a certain foundation for textile industry which has greatly developed during the 30 years after liberation. Now the textile industry includes wool, cotton and hemp textile and 10 more other trades, such as silk, chemical fiber, printing and dyeing, knitting, reproduction, textile machinery and textile materials. There are now 4,958 textile enterprises employing 3.1 million workers and staff members. For cotton textile, there are 16.6 million spindles and 510,000 looms, being 2-8 times those of the early post-liberation period. More than 120 cotton textile mills in the country have 50,000-100,000 spindles. The chemical fiber industry has developed from scratch and the amount of chemical fibers produced in China accounts for 9 percent of all its textile raw materials.

In 1979, the Party Central Committee and the State Council gave priority to the development of light and textile industries and gradually readjusted the proportionate relationship between light and textile industries on the one hand and heavy industry on the other. The state imported the required raw materials and some key equipment for developing the textile industry, and gave priority to this industry in the supply of power, fuel and raw materials. These measures have greatly helped promote the growth of the textile industry.

The total textile industrial output value in 1979 already accounted for 11.8 percent of the total national industrial output value, and was 9.5 times that of 1949.

State production plans for 10 major items, including chemical fiber, cotton yarn, cotton fabrics, printed and dyed fabrics, woolen fabrics, woolen yarn, gunny bags, silk and silk fabrics were all overfulfilled. The output of cotton yarn was 2.63 million tons, a 10.5 percent increase over that of 1978; that of cotton fabrics, 12.15 billion meters, a 10.2 percent increase over that of the previous year; that of chemical fibers, 326,000 tons, a 14.7 percent increase over that of the previous year; and that of silk fabrics, 663.45 million meters, an 8.7 percent increase over that of the previous year.

Many localities have paid great attention to the quality of products and launched campaigns to raise the quality and to produce brand-name products, besides holding various types of exhibition and sales meetings, meetings for the selection of samples before deciding on production, and the trial operation of retail stores to help improve the quality and increase the designs and varieties. The proportion of cotton yarn and cotton fabrics above grade 1 and first class in stock was 98.57 percent and 95.62 percent respectively, which were the best records in history. In the nationwide textile quality meeting, 113 varieties of products were formally recognized as brand-name products, while 38 other varieties won fine-quality prizes from the state.

Along with the developing production, production costs were decreased and profits increased. The annual taxes paid and profits earned increased by 15 percent over that of the previous year. Foreign exchange earnings from the export of textile goods also increased by 33 percent.

Outstanding achievements have also been won in tapping potentials and renovation and transformation of equipment. The new productive capacity in various trades and undertakings in 1979 is reflected in the following figures: 65,000 tons of chemical fibers, 600,000 spindles of cotton yarn, 400 million meters of printed and dyed fabrics, and 20,000 spindles of woolen yarn. Facilities were also set up for processing 1 billion meters of cotton fabrics, and 200 million cotton suits after the antishrinkage treatment; and the fast resin finishing of 400 million meters of cotton-decron fabrics.

A Number of Important Textile Projects in Operation

In 1979, active readjustment was made in capital construction for the textile industry of China in order to concentrate the available resources for the protection of key projects and to insure that they can be completed and commissioned. Thus nine large and medium-size projects, scheduled to be completely or partially commissioned in 1979, have been all completed and put into trial operation.

In June 1979, the Shanghai General Petrochemical Plant was formally taken over by the state and began its operation. This is a large complex mainly for the production of synthetic fibers with petroleum as the raw material. It is made up of two chemical plants, three fiber plants, one plastics plant with a total of 18 sets of equipment to form three production lines for ethylene, prophylene and arene. Its designed final products are: chemical fibers, 102,000 tons; plastics of polyethylene from high pressure process, 60,000 tons; and some oil and chemical raw materials. Among these 18 sets of equipment, 9 of them were imported, while the remaining 9 sets and the other equipment for the thermopower plant, the water pumping station, the machinery repair plant and the sewage disposal plant were all made in China. In 1979, 80,000 tons of chemical fibers were produced by this plant.

Liaoyang General Petrochemical Fiber Plant is a large complex producing diversified varieties on a large scale. The main sets of technical equipment were imported from France, Italy and West Germany. There are altogether 23 sets of production equipment, and when they are all completed, there will be annual output of 86,000 tons of dacron material (polyester fiber); 45,000 tons of polyamide fibers (nylon 66 "monomer"); and 70,000 tons of plastics. By the end of 1979, more than 94 percent of the construction project was completed, and the plastic polyamide fibers and polyethylene produced were up to the standard. The dacron and polyamide drawnwork production line was also in trial operation. The Dandong and Acheng Dacron Mills, in collaboration with this project, were also completed and in operation.

After trial operation in several stages in the first half of 1970, the Sichuan Vinylon Mill, with a designed capacity of 45,000 tons of polyvinyl alcohol fibers, was able to complete the whole work process on 14 December, and produce up-to-standard polyvinyl ether and polyvinyl alcohol fiber. With natural gas as raw material, this plant has part of its chemical equipment imported from France and Japan.

Expansion of Textile Export

Textile products are a major Chinese export commodity, and account for more than 20 percent of the total volume of our export every year. For a long time, Chinese textile products have received favorable comments in the international market for their fine quality and reasonable prices. In 1979, the textile trade in various localities made great efforts in expanding their export and earning more foreign exchange by stepping up the cooperation between industry and foreign trade and increasing the production of textile goods for export. Foreign exchange totaling 2.9 billion dollars was earned from this source, being 32.57 percent more than that of 1978. Among these products, the export of silk brought an earning of 800 million dollars, an increase of 27.88 percent over that of the previous year. The volume of woolen fabrics exported doubled that of the previous year.

To meet the world market demand by increasing the export of medium and high grade goods, the textile trade strengthened the technical transformation of the enterprises with the addition or remodeling of 10,000 sets of looms which provide broader width. When all these looms are in operation, the proportion of fabrics of extra width will be increased from 30 to 40 percent in the exported fabrics. The textile industry also imported more than 600 sets of advanced equipment for spinning, weaving, printing and dyeing and finishing, and increased the production of medium and high grade textile products for export. Furthermore, all textile enterprises made great efforts to design new products and to introduce new varieties and fashions for their exported goods. Printed designs on silk and cotton fabrics have added to the features of oriental art. Even such minor items as handkerchiefs have overprinted floral designs, set off by embroidery, or a jacquard open weave with cutoff motifs. A number of enterprises have produced fabrics according to the customers pattern, or printed them according to the supplied designs. Their work is well received by foreign customers.

The packaging of exported textile products also showed remarkable improvement in 1979. Some garments are now exported in hang-up packs to avoid crease and others are in plastic packs giving a clear view of the contents. Some matched sets of fabrics are attractively boxed in transparent blister wraps for the convenience of customers and as a means of business promotion.

Textile Products Exhibition and Sales Meeting Held on National Day by 13 Provinces and Municipalities

A textile products exhibition and sales meeting was held in Beijing from 20 September to 10 October 1979 to celebrate the National Day. The participants were representatives from Beijing, Shanghai, Tianjin, Jiangsu, Zhejiang, Shandong, Liaoning, Sichuan, Hebei, Henan, Hebei, Guangdong and Shaanxi. The meeting was held in 11 department stores and drapery stores including Beijing Department Store, Dongfeng Market, Dongsi People's Market and Xidan Department Store.

The textile products on exhibition and for sale were cotton fabrics, chemical fiber fabrics, woolen fabrics, silk and so forth totalling 26 categories of 2,000 varieties and more than 6,000 designs. Some of them had won gold or silver medals from the state for fine quality. From Shanghai were woolen fabrics, silk quilt coverings and interior decorative curtains. There were also colored chemical fiber fabrics from Wushi, corduroys from Changzhou, silk from Suzhou and Hangzhou, dacron-wool fabrics with designs and pleated skirts with transferred printing from Beijing; sports shirts and dacron knitwears from Tianjin, printed fabrics and mercerized bedsheets from Hubei, dacron knitted garments from Guangzhou; and so forth. All these items were welcomed by the customers.

This exhibition and sales meeting was jointly sponsored by the Ministry of Textile Industry and the Ministry of Commerce for the purpose of promoting textile production, raising the quality of products, increasing the designs and varieties, and enlivening the market on that festive occasion. The volume of business transacted during this period reached 6.83 million yuan.

Brand-Name Textile Products

From 17 to 26 July 1979, the Ministry of Textile Industry held a national conference on the quality of textile products in Anshan Municipality, Liaoning Province. In the conference, 113 products were formally designated as brand-name products of the textile industry.

These brand-names were given to products recommended by various localities after selections of the best among the best and subject to a final evaluation. Among these brand-name products were some long well-known products, such as the "Stork" 4040 poplin of Shanghai; the "Lotus Lantern Dance" corduroy of Changzhou; the "Snowy Lotus" woolen sweater of Beijing; the "Flying Child" Brand brocade from artificial silk of Beijing; the "Plum Blossom" 38-count fine-spun cotton sports shirt of Tianjin, the "Three Golden Cups" printed silk fabrics, and so forth. Among the new brands are the "Mandarin Ducks" bedsheets of Shashi, Hubei; and the "Plum Blossom" mulberry silk of Shanxi and Zhejiang. It was particularly gratifying that even some little known mills have also produced new brand-name products. Among them are the "Sweet City" 1818 grey cloth of Sichuan's Neijiang Cotton Textile Mill; and the "Burning Prairie" 4545 decron of Shaanxi No 11 Cotton Mill.

This was the first time of any brand-name being given after selection and evaluation in the textile trade since liberation as well as the first time in many years of some units being commended for their fine quality and the increased designs and varieties of their products. The criteria used by the Ministry of Textile Industry for the products to be qualified for brand-names are that the quality of products must be able to match up with that of similar products at home and abroad of the advanced level; that the production of these items must have a history of at least 5 years; and that the products must have some unique feature. All the 113 products conformed to these criteria.

Progress of Self-Twisted Yarn Spinning

Self-twisting spinning is a new method of spinning at low speed but with high yield. Compared with the ordinary method of spindle spinning, self-twisted spinning can save 47.75 percent of power, while the output can be 15-25 times higher. The labor can also be reduced by a margin of one-third to one-half, and the area required can be reduced by 30-80 percent. Yarns of lower count can be produced out of the same raw material if this method is used.

Because of the above advantages, rapid progress has been made in the research and experiment of self-twisting spinning in our country since 1975. In 1978, the state conducted an appraisal of the plush self-twisting spindles, and in 1979, another appraisal was carried out on the use of self-twisting spindles for medium fibers. Using their own processing facilities, many localities in the country have designed and manufactured a large number of the required machines and by the end of 1979, there were 16 fairly large intermediate experimental, research and industrialized production centers. Their main products include plush, worsted, medium fiber, bulked acrylic yarn, and decron-hemp. Among them, the production of plush, medium fibers, and dacron-hemp is no longer dependent on foreign wool. There are now high-count dacron-hemp materials, woolen fabrics with square designs, plush, bulked acrylic scarves, dacron-acrylic fabrics with designs, palace and imitation woolen sweaters, which are of good quality and selling well.

Thirty-Two National Technical Innovations Used in Transforming Nantong Cotton Mill No 1

[Article by Zhong Xiushi [6774 4423 1395]]

Nantong No 1 Cotton Mill of Jiangsu Province is one of the oldest mills built by China itself. The No 1 Spinning Workshop was built in 1889. Despite repeated transformations, it still failed to meet the requirements of production development or to reach the advanced world level. An overall transformation was carried out in 1974. According to the plan, the rebuilding of the mill should not interfere with its efforts to fulfill the production task. The project was to proceed in two stages and four sections, and, according to the original plan, should be completed in 1980. After the downfall of the "gang of four," and thanks to the leadership of the higher authorities, its operation began ahead of schedule in August 1977. An intermediate trial operation began in 1978 and the final appraisal was made in 1979.

The special features of this workshop are: a fairly centralized application of the 32 national innovations resulting in the use of new efficient techniques; better working conditions with reduced labor intensity; and higher labor productivity. During the intermediate test, the operation had reached the following technical levels: average per-unit output: 39.19 kilograms; and breakage: 20.2 strands/1,000 spindle-time; quality: 100 percent first class grade one; dust content: 2.51 milligram/cubic meter (maximum average of four workshops for carding, drawing, coarse and spun yarns not more than 3 milligram/cubic meter); labor required: 3 labor/piece (equivalent to 29.16 (20^s) according to the Japanese way of calculation); electricity consumption: 273 kwh/piece. These levels are comparable to the Japanese mass production level.

Special technical features of the workshop: (1) Lower end-breakage rate, a broader view of the machine and 24-hour continuous operation (with half an hour's meal time assured for workers of each shift). (2) Automatic transport of semi-finished or finished products. (3) Workers operating the spindles using a sliding carriage instead of walking. (4) High speed, large-scale winding and continuous operation (cotton sorting: 500 kilograms/hour; carding: bobbin ø406 x 914, 200 meters/minute; spun yarns: spindle speed 14,000-14,600 rotations/minute; shaping ø44.45 x 19). (5) Workshop building with wide spans between pillars (between main pillars: 17.6 meters x 8.6 meters; between side pillars 13.4 meters x 8.6 meters), good lighting (area of skylights amounts to 25 percent of roof area); temperature variation as small as 1°C (wooden structure of house provides good air circulation).

Overall transformation of the workshop is of great reference value for the technical transformation of old factories and the building of new ones throughout the country.

Electronic Industry

[Article by Li Anding [2621 1344 1353]]

General Description

China's electronic industry has become a fairly complete new industrial system with different departments. According to the makeup of its products, there are consumer goods, means of production and products for civilian use as well as national defense. At present, the majority of electronic products are for civilian use, and its ratio is continuing to rise.

By the end of 1979, there were in China 285 units producing complete sets of radios and television sets, including more than 80 TV set plants. The equipment for voice broadcasting and television was then adequate for the requirements of radio and television stations and research and production of color TV equipment were successful. In 1979, China produced 1.33 million TV sets, being 2.57 times that of 1978, and 13.81 million sets of radio receivers, an increase of 18.2 percent over the number of 1978. The outputs of tape-recorders and gramophones were 2.8 times and 2.7 times those of 1978 respectively.

There are now approximately 730 varieties of electronic products as a result of the popularization and application of electronic technology in China. In 1979, the total output was more than 680,000 sets, including the sets used in civilian radio stations, telephone exchange equipment, telephones, pocket calculators and other electronic products for agriculture, forestry, industry, communications, culture and education, public health and various trades and undertakings.

The production of electronic computers in China has made fairly good headway since its inception in 1958. After a successful research, integrated circuit computers of the 100 and 200 series were in serial production in the past several years. The 100 series is a small type, and the 200 series is a large or medium-size type. In 1979, research and production of integrated circuit with 5 million operations per second were accomplished. Computers capable of 20 million operations per second is being trial produced.

The production of basic electronic products has also rapidly developed. Among them are electronic tubes, semiconductor articles and parts, integrated circuits, electronic elements, electronic measuring instruments and special wireless equipment. There are 2,000 varieties of electronic elements, and the annual productive capacity is 3 billion pieces. There are more than 400 types of integrated circuits, and the annual productive capacity is 35 million sets.

In 1979, the quality of electronic industry in various provinces, municipalities and autonomous regions carried out serious readjustment and reorganization among their affiliated enterprises according to the principle of specialization and coordination with great success.

New Construction of Shaanxi Color Kinescope Plant

Construction of the Shaanxi Color Kinescope Plant, which will have the technical level of the 1970's, was started in April 1979 in Hanyang Municipality of Shaanxi Province, and the work is proceeding rapidly.

The complete set of equipment for this project was imported from Japan, while the auxiliary projects were undertaken by China itself. The construction site of this plant covers a total area of 3,400 square meters, and the plant will consist of four main workshops for the production of fluorescent powder, shading covers and glass, and for general assembling. This plant is comparable in scope to the fairly large enterprises of the same type in the world. It is estimated that this plant will be completed and ready for operation by the end of 1981. Then, its annual output will be 960,000 14-inch and 22-inch color kinescopes. The production techniques for these color kinescopes are based on a collection of all the fine features of foreign products. The kinescopes will have good clarity, brightness, contrast and color effects with low power consumption and good stability.

By the end of 1979, the main structure of the four main workshops had already been basically completed and sealed up, while the building and equipment of auxiliary workshops are being stepped up. After the completion of the plant's main structures, testing and adjustment of the equipment will be completed in March 1981.

National Evaluation of the Quality of Black-and-White TV Sets and Radio Receivers

In September 1979, the Fourth Ministry of Machine Building and the State General Bureau of Broadcasting and Television held in Nanjing the second meeting to evaluate the quality of black-and-white TV sets and the seventh meeting to evaluate the quality of radio receivers, and awarded prizes to the advanced units for the fine quality of their products.

Among the products evaluated were 91 types of transistor and electronic tube black-and-white TV sets produced by 56 enterprises and 197 types of radio receivers produced by 91 enterprises from various provinces, municipalities and autonomous regions. After a careful evaluation, 26 types of TV sets and 73 types of radio receivers won prizes.

There were 16 types of TV sets receiving prizes. Among the 9-inch sets were: "Feiyue [Flying Leap]," "Yingxiong [Hero]," "Xinghuo [Star-fire]" (2 types) and "Kaige [Triumphant Song]" brands of Shanghai. The 12-inch sets were: "Feiyue [Flying Leap]," and "Jinxing [Gold Star]" brands of Shanghai; "Xihu [West Lake]" brand of Zhejiang, "Juhua [Chrysanthemum]" and "Shenyang" brands of Liaoning; "Mudan [Peony]" brand of Beijing, "Kongque [Peacock]" and "Qingsong [Green Pine]" brands of Jiangsu; and "Qingdao" brand of Shandong. The 14-inch sets were

"Shaofeng [Peak of Shaoshan]" brand of Hunan, and the 19-inch set was "Feiyue [Flying Leap]" brand of Shanghai.

Prizes of the first order were given to 23 types of radio receivers. The foremost among them were: "Chunlei [Spring Thunder]" brand transistor radios of the second-grade and third-grade mesa types, and fourth grade of the pocket type; the "Hongdeng [Red Lantern]" brand radio with electronic tubes of the third-grade mesa type; the "Haiou [Sea Gull]" brand fourth-grade portable transistor radio of Shanghai; and "Xiongmao [Panda]" brand third-grade transistor radio.

This evaluation was very strict in its demands and was based on the practical needs of consumers and the dependability and stability of the products.

Light Industry

[Article by Shi Baohua [2457 1405 5478]]

General Description

China's light industry has developed steadily since the founding of the People's Republic, and is now an important industrial department with a fairly complete assortment of products, a rational geographical distribution and a fairly high level of production process. The total light industrial output in 1979 was 198 billion yuan, being 22.8 times that of 1949. The outputs of many light industrial products have increased rapidly. For example, the average annual output of wrist watches has increased by 64 percent; bicycles, by 25 percent; sewing machines, by 18 percent; synthetic detergents by 24 percent; photo-sensitive film, by 33 percent; and plastic wares, by 28 percent. The quality of many products continues to improve along with the increase of designs and varieties. The development of new light industrial trades has been phenomenal as shown by the production of synthetic detergents, synthetic fatty acid, plastic wares, synthetic leather, synthetic spices, wrist watches, optical glass, light-sensitive materials, household electric appliances and so forth. The development of these trades has filled a big gap in China's light industry.

Along with the growth of light industry, the export of Chinese light industrial products has also continued to increase. From 1950 to 1978, the average annual increase of foreign exchange earnings from the export of light industrial goods was 16.2 percent. In 1979, the amount of foreign exchange earned from the same source again increased by 24 percent over that of 1978. The volume of light industrial export amounted to one-quarter of the total national export.

In accordance with the policy of national economic readjustment in 1979, the state adopted a series of measures, such as increased loans, priority in the supply of energy and raw materials, and so forth, to speed up the development of light industry. In the same year, the total light industrial output value exceeded that of 1978 by 9.6 percent. For example, the output of machine-made paper and paperboard was 4.93 million tons, an increase of 12.3 percent; bicycles, 10.09 million, an increase of 18.1 percent; sewing machines, 5.87 million, an increase of 20.8 percent; wrist watches, 17.07 million, an increase of 26.4 percent; sugar, 2.5 million tons, an increase of 10.1 percent; and cigarettes, 13.03 million crates, an increase of 10.2 percent over the previous year's. The quality of products was generally raised. Among the 133 items produced by 122 key enterprises of 11 trades and examined by the Ministry of Light Industry, the quality of 118 or 89 percent of them showed better results as compared with that of the previous year; 18 of them won gold medals and 27 others won silver medals from the state for their good quality.

New Light Industrial Products Actively Developed

In 1979, the light industrial departments of China attached great importance to the improvement of quality and the increase of designs and varieties, and light industry enterprises in various made great efforts in upgrading and replacing their products by increasing the production of new ones. More than 6,000 new varieties were trial produced in the same year. There were also 100,000 new varieties and new designs, and one-third of them have been in serial production.

Among these new products were bicycles with speed gears; electric multiple-purpose sewing machines capable of sewing 20 different designs; quartz wrist watches with a time difference of only about 1 or 2 seconds each day; small refrigerators of fairly low prices and suitable for the present standard of living in the country; automatic shutoff electric fans; thermos jars with a pumping cap; electric organs which can imitate the timbres of more than 20 foreign musical instruments and gives good resonance; the tasty and refreshing drink "Xingfu Kela [Happy Cola]"; the all-weather plastic umbrellas with attractive floral designs; and the enzyme laundry powder capable of removing sweat stains, milk stains and all dirts containing protein; and so forth.

The other important new products are: laundry machines, air conditioners, electric water heaters, electronic cigarette lighters, irons with regulated temperature, pocket warmers, micro-blowers and multiple-purpose hair-care appliances produced by the household electric appliances trade; the wide-mouth ice water jugs, wire glass tea sets, and enamel pans produced by the glass and enamel ware trade; the imitation drawnwork, wallpaper, rugs, decorative boards, TV enlarging screen and plastic wrapping sheets produced by the plastics trade; and the easily dissolved milk powder, easily dissolved bean-powder and easily served food items produced by the food trade, are all well received by the consumers.

Four Hundred Twenty-Five Light Industrial Products of Fine Quality

In 1979, the Ministry of Light Industry awarded certificates of fine quality for 425 products of 27 trades, including those of bicycles, sewing machines, garments, shoes and hats, musical instruments, plastic products, detergents, hardwares, household electric appliances, enamel and glass utensils, artistic work, paper and food.

Apart from those traditional brand-name products from Shanghai, Tianjin, Beijing and other large cities which had already won national medals for their fine quality, a large portion of these 425 products were produced in small and medium-size towns of various provinces and municipalities. They are, for example, the "Crystal" brand glass utensils of Dalian in Liaoning; the "Camel" brand enamel utensils of Xi'an in Shaanxi; the "Silver Lake" brand men's shirts of Wuxi in Jiangsu; the "Vanguard" brand badminton of Shaoxing in Zhejiang; the "Pigeon" brand plastic shoes of Fuzhou in Fujian; the dictionary paper of Huangxian County in Shandong; the "Pearl" brand buttons and buckles of oyster-shell color in Dangtu in Anhui; and so forth. All these products, which have won the certificate of fine quality, are in serial production, and are well received by the customers because of the fine quality of advanced levels at home and abroad.

Eighteen Famous Chinese Liquors

In September 1979, the Ministry of Light Industry held in Luda Municipality the Third National Meeting for the Evaluation of Liquors; and 18 different brands were rated as liquors of national fame.

These 18 brands include white wine, port wine, yellow wine and beer.

The white-wine category includes: Maotai (of Renhuai County, Guizhou), Fenjiu (of Xinghuacun, Shanxi), Wuliangye (of Yibin, Sichuan), Jiannanchun (of Mianzhu, Sichuan), Gujinggongjiu (of Boxian County, Anhui), Yanghe Daqu (of Siyang, Jiangsu), Dongjiu (of Zunyi, Guizhou), and Laojiao Dequ (of Luzhou, Sichuan).

The famous port wines are: Red Port wine (of Yantai, Shandong), Chinese Red Port Wine (of Beijing); White Port Wine (of Shacheng, Hebei), Minquan White Port Wine (of Minchuan, Henan), Yantai Weimeisi (of Yantai, Shandong), Yantai Gold Medal Brandy (of Yantai, Shandong), and Zhuyeqing (of Xinghuacuan, Shanxi).

The famous yellow wines are: Shaoxing Jiafangjiu (of Shaoxing, Zhejiang) and Longyan Chenganjiu (of Longyan, Fujian).

The famous beer is Qingdao Beer (of Qingdao, Shandong).

There are 47 others rated as fine quality liquors of China.

Construction Industry

[Article by Xu Yaozhong [1776 5069 0022]]

General Description

In 1979, all types of work under the General Construction Engineering Bureau of China made outstanding progress. The area of buildings completed by enterprises owned by the whole people and the collectives amounted to some 82.94 million square meters, and the value of the completed buildings and equipment amounted to some 12.28 billion yuan. Both the area and the value increased by a wide margin over those of the previous year. All localities attached great importance to the results of investments, with the result that the construction period was greatly reduced and the quality was generally improved. The main projects completed under the charge of the construction industry departments in 1979 are: the waiting hall in the International Airport of the capital, the Sichuan Vinylon Mill, the Shanxi Vinylon Mill, the Heilongjiang Dacron Mill, the Nanning Cotton Textile Mill, the Hankou Paper Mill, the Yueyang Paper Mill, the Yunnan Chemical Plant, the Shizuishan Power Plant, the Wuxi Movie Films Plant, the Zhanjiang Ocean Fishery Base, the Jinan Cold Storage, the Yunnan Observatory, the Henan People's Hall, the Harbin Stadium, the Yunnan Industrial College, the Xiangtan University, and the North China Agricultural College. In 1979, the construction engineering system paid particular attention to the construction of light and textile industries, electric power, coal and construction materials; and workers' dormitories and schools. It played an active role in strengthening the weak links of the national economy and improving the people's living conditions, and showed fairly good results in the construction projects connected with tourism.

Before liberation, China's construction industry was very backward. In the 30 years following the founding of the People's Republic, the construction industry departments have undergone great development and created a great deal of wealth for the state. In these 30 years, the value of their completed work amounted to more than 95 billion yuan, and some 670 million square meters of housing of various types were completed. At present, these departments have some 3.4 million construction workers, including 1.66 million for the enterprises owned by the whole people and 1.74 million for those owned by the collectives.

Overall Fine Quality Construction Contest

Construction engineering of fine quality, high efficiency, low production cost, and "civilized" work are called overall fine quality construction. The first unit to be so qualified was Beijing Construction Company No 6 in 1977. The State Capital Construction Commission, the State Labor Bureau, the All-China Federation of Trade Unions and the People's Construction Bank of China summed up the experiences of the Beijing Construction Company No 6 and held an overall fine quality construction contest among the three cities of Beijing, Tianjin and Tangshan with outstanding success. In 1979, after the establishment of the State General Construction Industry Bureau, the experiences of the overall fine quality construction contest continued to be popularized and many provinces, municipalities and autonomous regions, as well as construction bureaus affiliated with the General Construction Bureau continued to organize these contests. At present, the overall fine quality construction projects, formerly involving only thousands of square meters have been enlarged to involve tens of thousands of square meters, and the scope of these projects have developed from civilian construction to national industrial construction and from single-item construction to overall fine quality architectural complex. In 1979, Beijing, Tianjian and Tangshan completed more than 690 overall fine quality construction projects and the area of construction exceeded 1.74 million square meters. Shanghai completed 567 such projects with a total area of 940,000 square meters, and the overall fine quality construction projects completed by Liaoning, Sichuan, Hunan and Jiangsu, and the No 1 and No 3 Engineering Bureaus directly affiliated with the General Construction Bureau amounted to 20 percent of all the construction projects in these areas.

Changzhou and Nanning as Experimental Cities of Construction Industrialization

The industrialization of construction in China is still in the experimental stage. Experiments in Changzhou Municipality of Jiangsu Province and Nanning Municipality of Guangxi Zhuang Autonomous Region, the two key cities, have been an initial success.

In Changzhou Municipality, experiments of industrialization were carried out mainly on one-story factories, with 34 types of molded boards, 43 types of structural parts and 16 types of units, all of finalized designs. The outer walls are made of large prefabricated panels. All these can be organized to form production workshops to meet 322 different requirements. The weight of this type of structure, the labor involved, and the construction period were reduced by 15 percent, 20 percent and more than 50 percent respectively. Under this system of construction, the labor productivity in the construction units of Changzhou Municipality can be raised by 33 percent, and the average area of completed work by each person is more than 3.79 times that of the national average. The speed of construction is also increased, and the building of factories of 10,000 square meters takes only 7 months.

In Nanning Municipality, experiments are carried out mainly on the construction of residential houses with large hollow concrete slabs. These slabs are of great technical and economic value, because it requires only simple production process and can be undertaken with indigenous methods and quickly completed. Generally, a 6-story building can be completed in 3 months. The industrialization of large concrete slab houses is beginning to take shape, and serial production is now possible. In 1979, a floorspace of more than 110,000 square meters was built, being 43.6 percent over that of 1978. The structural parts produced in 1 year can be used for building 200,000 square meters of residential housing. Special teams for this type of building have been organized and each person can complete 107 square meters of floorspace of the value of 10,200 yuan.

Several Systems of Construction Industrialization

In 1979, four different systems of industrialized construction suitable for China's characteristics were developed.

1. The large mold plate system. The method is to build the walls with the in-situ concrete method. At present, there are three types of houses built this way: in-situ concrete for the interior walls and bricks for the outer wall (called "in-situ interior and brick exterior"); in-situ concrete for the interior walls and prefabricated boards for the exterior walls; and in-situ concrete for both interior and exterior walls (called "complete in-situ"). The advantages of this type of structure are: good technical and economic results; high efficiency work; less investments; simplicity of method; and ability to withstand earthquake. This system is being used in 16 provinces, municipalities and autonomous regions, and in 1979, some 1.5 million square meters of floor space were completed throughout the country. According to statistics in Beijing, Tianjin, Shaanxi, Jiangsu and Liaoning, there is now a productive capacity for 4.8 million to 5.5 million square meters of large mold-plate multiple-story houses.

2. The system of large board construction. Under this system, large prefabricated wall boards are assembled on this spot. This method is being used in 26 provinces, municipalities and autonomous regions, and some 850,000 square meters of floorspace was completed throughout the country in 1979. This type of structure is largely built in the form of assembling. Therefore, not much on-the-spot labor is required, and the work can be quickly completed. Since it is little affected by seasonal changes, this method is particularly adapted to cold regions where construction of this type can go on throughout the year.

3. The system of frame-and-panel construction. Prefabricated or in-situ pillars or wooden pillars are used to support the weight of the structure, and gypsum boards, cinder boards, asbestos boards, aerated concrete and compound boards of light weight are used as materials for building the walls. In 1979, some 270,000 square meters of frame-and-panel houses were built throughout the country, and in Suzhou, Jiangsu Province, the first base with a productive capacity of enough materials for building 100,000 square meters of frame-and-panel houses each year has been established. The advantage of the frame-and-panel house is that the structure itself is light and can be easily put up. This system of construction is being tried out in 11 provinces, municipalities and autonomous regions.

4. The system of block construction. The blocks used are made of concrete, coal cinder, gangue and other industrial wastes, and the use of these blocks to build walls is a simple way of industrialized construction, or an improvement upon the use of clay-brick and concrete. The making of blocks is fairly simple, and the production cost is low. Since there is a great deal of industrial wastes to be used, this system of construction can be used in any place. Hence it can be easily popularized. In 1979, some 1.07 million square meters of this type of housing was completed throughout the country. According to incomplete statistics, there are now more than 100 block manufacturing factories in 13 provinces and municipalities with a productive capacity of 1 million cubic meters.

[Text] Railways

Railway Construction in China

Since the state was founded, China's railways have undergone 30 years of construction and redevelopment and have begun to constitute the framework of a national railroad network.

In a 73-year period in old China, only somewhat more than 20,000 kilometers of railroads were built. Their design was obsolete and backward, and most of the routes were in coastal regions, which was an extremely irrational layout of the network. Since the state was founded, and under unified state planning and management, by the end of 1979 the nation (excluding Taiwan Province) had 51,525 kilometers of railroads in operation (including some local railways). In addition, there were 6,287 kilometers of newly constructed two-track lines, 1,031 kilometers of electrified railway, and 42 newly constructed or expanded rail centers. The southwestern and northwestern regions, which in the past were traffic bottlenecks, now have the newly constructed Cheng-yu [Chengdu-Chongqing], Bao-cheng [Baoji-Chengdu], Lan-xin [Lanzhou-Xinjiang], Chuanqian [Sichuan-Guizhou], Guikun [Guilin-Kunming], Chengkun [Chengdu-Kunming], Xiangyu [Xiangfan-Chongqing] and Xiangqian [Hunan-Guizhou] lines, so that railroads west of the Beijing-Guangdong rail line have increased their share of total mileage from 19.5 percent in the early days of the state to 45.3 percent, and are making an active contribution to improving China's railroad network situation and to linking together coastal and border transportation. Now every province, municipality and autonomous region with the exception of Tibet has railways.

In the 30 years since the founding of the state, China has built 24,526 kilometers of railroads (mainline track laying), an average of 817.5 kilometers a year; in busy double track sections more than 5,800 kilometers of automatic block signal lines have been constructed, a length equivalent to 11 percent of the total mileage in service nationwide; on the main trunk lines, 1,432 electrified marshaling yards have been constructed.

During the construction process, many new technologies, designs and materials have been popularized and utilized, which has made a major contribution toward improving rail line quality and transport efficiency. The completion and opening of the

Chengdu-Kunming railway and the Nanjing railway bridge over the Yangtze marked the attainment of a new level by railroad construction in China. At present the length of rail lines in operation has increased by 1.3 times over the mileage shortly after the state was founded.

Railway Transport in 1979

In 1979 in railway transport departments overfulfilled their annual state transport assignments and new records were set in both passenger and freight transport.

The total number of passengers carried was 856 million, which was 104.4 percent of the planned figure for the year and 6 percent above the previous year's figures; the overall passenger turnover figure was 121.4 billion passenger-kilometers, up 11.3 percent from the previous year; the average distance traveled per passenger was 142 kilometers, an increase of 7 kilometers over the previous year.

As the work of national economic readjustment has proceeded, railroad freight hauling has turned over a new leaf. The share of such long-haul commodities as coal has increased, the national commodity transport figure has reached 1.094495 billion tons, 101.4 percent of the planned figure for the year, and up 1.9 percent from the previous year; every day the entire system loads 62,789 railcars, an increase of 555 cars from the previous year; the freight turnover figure for the entire system was 558.8 billion ton-kilometers, an increase of 4.8 percent over the previous year; the average commodity haul was 510 kilometers, 14 kilometers longer than in the preceding year. The commodity turnaround time for the entire system was 3 days.

Railroad transport has been implementing the policy of assigning priority to agriculture, light industry and heavy industry in that order, and has given preference to transport of agricultural support commodities, light industrial and market goods, and foreign trade and export goods, and has made a vigorous effort in critical commodities such as coal, obtaining rather good results. The quantity of coal dispatched in the entire system was over 410 million tons, 1.5 percent above the annual plan figure. Some 60 million tons of coal were shipped out of Shanxi, a record year's figure, and the total quantity of coal shipped to the Northeast was almost half again as great as in the preceding year, reaching 10 million tons. The overfulfillment of the coal transport targets produced a warm situation in industrial and domestic use of coal. The quantity of smelted materials dispatched was more than 20 million tons, equivalent to 103 percent of the annual plan figure, and equivalent to the actual figure for the previous year. The amount of petroleum shipped was over 59 million tons, 105.9 percent of the annual plan figure, but 3.1 percent below the previous year's figure. The amount of wood products hauled was over 39 million tons, 104 percent of the annual target, and the quantity of wood products shipped in from the Northeast was over 10 million tons, up 500,000 tons from the previous year. Transport of such agricultural, light industrial and agricultural-support commodities as grains, chemical fertilizers and agricultural pesticides, agricultural tools, fresh perishables, daily-use manufactured goods and miscellaneous items was up from the previous year, while transport of export commodities increased by a third.

Compared with 1950, passenger transport for the whole system in 1979 was up 4.5 times, and passenger turnover had increased by 4.7 times. The amount of freight hauled up was 10 times, and freight turnover had increased 13 times. Currently railroads account for 61.7 percent of the total passenger transport turnover by modern transport facilities nationwide, and 51.3 percent of total freight turnover. Rail transport represents a main component of China's unified socialist transport network, and has an absolute majority of numbers of passengers and quantities of freight transported.

Not only are passenger and freight transport quantities increasing, but the quality of transport work has clearly improved. In 1979 the on-time departure rate for Chinese passenger trains was 99.1 percent and the on-time rate in transit was 92.9 percent, an increase of 0.2 percent over the previous year; the on-time departure rate for freight trains was 92.8 percent and the on-time rate for freight trains in transit was 89.4 percent, an increase of 2.2 percent over the preceding year.

There has been considerable progress in safety, with a 13.6 percent decrease in grave and serious accidents from the previous year; the number of grave and serious accidents in freight transport was down 58.4 percent from the previous year.

At the end of 1979, the total operating railroad mileage nationwide was 49,808 kilometers. These rail lines belonged to 20 railroad bureaus: Chichihar, Harbin, Jilin, Shenyang, Jinzhou, Beijing, Taiyuan, Huhehot, Jinan, Zhengzhou, Wuhan, Xi'an, Shanghai, Nanchang, Guangzhou, Liouzhou, Lanzhou, Chengdu, Kunming and Urumchi.

Railroad Capital Construction in 1979

In 1979 railroad construction adhered to the policy of readjustment, and technical redevelopment of existing railroads was made the focus of readjustment. During the year there were 61 medium and large new and continuing construction projects, including new construction of 8 double track lines among them the Jinpu [Tianjin-Pukru], Beijing-Guangzhou and Jiaoji [Jiaozhou-Jinan] railroads; 5 electrified railroads including the Shitai [Shijiazhuang-Taiyuan], Longhai [Gansu-Qinghai] and Xiangyu lines; the construction of 5 rail centers including those in Beijing and Wuhan; and 3 joint projects including the Baoshan Steel Mill in Shanghai; and continued construction work on 27 projects including the Wangan [Anhui-Jiangxi], Zhiliu, Shatong, Qingzang [Qinghai-Tibet railway] and Jiujiang Yangtze River railway bridges as well as some other engineering projects. Of the large and medium projects, the 192-kilometer double track section of the Longhai railroad between Zhengzhou and Shangqiu was handed over and put into operation; the 70-kilometer double track section of the Shide railroad between Tuxianzhuang and Xincheng was completed and put into operation; the southeastern link of the Beijing rail center was put into operation; the 120-kilometer electrified section of the Shitai railroad between Shijiazhuang and Yangquan was essentially completed; the 170-kilometer section of the Fuqian line between Fulidun and Jiansanjiang was ready to be handed over; and the track was laid and put into operation on the Qingcang [Qinghai-Xizang] line as far as Golmud. In addition the Shuangqiao dispatching yard of the Beijing rail center, the new Wudong marshaling yard of the Wuhan center and the dispatching yard of the Shijiazhuang center have all been handed over and put into operation.

In the past year [1979], 21.9 kilometers of bridges and 19.3 kilometers of tunnels were completed and 875 kilometers of new main trunk and branch lines and 215 kilometers of double track lines were constructed.

Construction of Electrified Rail Lines

In order to increase railroad transport capacity, to make comprehensive use of motive power resources, to decrease environmental pollution and to achieve the aims of low investment and high effectiveness, in 1958 China began the construction of electrified railways. By the end of 1979, two electrified railroads had gone into use, with a total length of 1,031 kilometers. In addition, 5 electrified railways with a total length of 2,274 kilometers are under construction.

The electrified lines which are already open are: the Baocheng railroad from Baoji in Shaanxi to Chengdu in Sichuan, with a total length of 670.7 kilometers; and the Yangan railroad, which starts at Yangpingguang in the central section of the Baocheng electrified railroad and ends at Ankang in the central section of the Xiangyu railway, a total length of 356.7 kilometers. The Longhai line is 3.5 kilometers long.

The electrified railways under construction are as follows:

1. The Shitai railway. Extending from Shijiazhuang to Taiyuan, with a total length of 235 kilometers, this is an east-west, double track modernization project. The electrification of the 120-kilometer section between Shijiazhuang and Yangquan had been essentially completed by the end of 1979, and it requires only application of electric power in order to go into operation.

2. The Xiangda railway. This extends from Xiangfan in Hubei to Daxian in Sichuan, a total of 646 kilometers. This is a section of the Xiangyu railway, an east-west trunk line; in 1979 the electrification equipment was installed on the 362 kilometer section between Xiangfan and Ankang.

3. The Baolan railway. This extends from Baoji in Shanxi to Lanzhou, a total of 511 kilometers. In 1979 the electrification equipment was installed on a 158-kilometer section from Baoji to Tianshui; roadbed improvements are under way on the section between Tianshui and Lanzhou.

4. The Chengyu railway. This extends from Chengdu to Chongqing, a total of 505 kilometers. The electrification facilities are being designed and roadbed improvements have begun.

5. The Fengda railway. This extends from Fengtai, Beijing City, to Datong, Shanxi, a total of 377 kilometers. The electrification facilities are being designed, and roadbed improvements are under way.

When these five new electrified lines are complete, China will have more than 3300 kilometers of electrified lines, including a 2,700 kilometer electrified network in the southwest and northwest, while construction of the electrified Shitai and Fengda lines in North China will double transport capacities.

The Qinghai-Xizang Railway

The Qinghai-Xizang Railway is an important trunk line linking China proper with the frontier regions, with a total length of 2,049 kilometers. As of the end of 1979, track for this line had already been laid past Ge'ermu, and a total of 846 kilometers was in operation.

The Qinghai-Xizang Railway begins in Xining city, Qinghai, and passes through Gangcha, Delingha, Golmud, Neichitai, Tuotuohe, Anduo, Naqu, Dangxiong, Linzhou and Mozhugongka to Lhasa, the capital of the Tibetan Autonomous Region. It passes through the Tsaidam Depression, and crosses such important mountain ranges as the Kunlun, Fenghou, Tanggula and Nianjing Tanggula ranges and such main rivers as the Ge'ermu, Chuma'er, Tongtian, Tuotuo and Lhasa rivers; much of the railroad is located in the Qinghai-Tibet Plateau, the "ridgepole of the world"; it is at an altitude of 4,000-5,000 meters for more than 930 kilometers of its length, so that it is the highest altitude railroad in the world.

The engineering geology of the right of way is rather complicated. In the southern part of the Tsaidam Depression there are a series of deserts, salt lakes, salinized soil areas and sand dunes; in the plateau area there is more than 570 kilometers of permafrost; and between Nuoqu and Dangxiong the basic earthquake intensity is 9 to 10. In addition, the air is thin over a large proportion of the route, the climate is severe and changeable, and the engineering difficulties have little precedent in world construction experience.

Utilization of Locomotives and Rolling Stock

Locomotives. At the end of 1979 the country's railroads had a number of locomotives 1.5 times greater than shortly after liberation. To aid in locomotive utilization and inspection and repair, locomotive types were decreased from 175 shortly after liberation to 54.

Initially steam locomotives were used for fast passenger trains on the main Changda, Shenshan, Jingshan, Jingguang, Jinpu and Huning lines, but they have now been completely replaced by internal combustion locomotives.

Because of the steady increase in the number of internal combustion and electric locomotives, some maintenance sections under the Guangzhou, Xi'an and Chengdu railway bureaus have begun experimenting with use of the "changjiao lu lunchengzhi;" [literally, long-distance transport rotational hauling system].

Internal combustion locomotives are already in use for passenger trains on the Chengdu-Kunming, Guizhou-Kunming, Qiangui [Quizhou-Guangxi], Guangjiu [Guangzhou-Jiulong], Nenlin, Jingyuan and Huning railways.

Internal combustion engines are also in use with freight trains on some sections of the Jingshan, Jingbao, Jingguang, Jinpu, Chuanqian, Lanxin and Jiangyu railways.

All passenger trains are pulled by electric locomotives on the Baocheng and Yang'an railways.

The weight of freight trains hauled on such main trunk lines as the Shenshan, Jingshan, Beijing-Guangzhou, Jinpu, Tongtuo and Huning lines has been increased from 1,600 tons shortly after Liberation to 3,500 tons, and an excess of 85 million tons was hauled during the year.

The daily distance traveled by freight engines was 412 kilometers, an increase of 8 kilometers from 1978; the average output was 723,000 ton-kilometers, up 9,000 ton-kilometers from 1978; locomotives consumed 109.5 kilograms of coal per 10,000 ton-kilometers, a decrease of 4.6 kilograms from 1978; the oil consumption of internal combustion locomotives per 10,000 ton-kilometers was 35.7 kilograms, a decrease of 1.9 kilograms from 1978; electric locomotives consumed 132.6 kilowatt-hours per 10,000 ton-kilometers, down 3 kilowatt-hours from the 1978 figure. Some 1.38 million tons of coal, 66 tons of diesel oil and 12 million kilowatt-hours of electricity were conserved during the year.

Railcars. 1. Passenger cars. At the end of 1979, the entire system has 2.9 times more passenger cars than shortly after Liberation. Since 1961 there has been a decrease from 38 models and 299 types to 30 models and 171 types. Currently express, through and fast trains all now use the new domestically produced models 22 and 23. Some 10,698 of the system's passenger cars, or 71 percent of the total number, have their own heaters and water heaters. Some 13,228 passenger cars are now fitted with ball bearings.

In order to maintain safety on passenger trains, the system of distributed responsibility for car maintenance is used in current maintenance and servicing, and every train carries a train inspector who is responsible for train safety from the point of origin to the destination. It is also required that 2 major servicings and quality inspections be performed every year, in the spring and fall. Grave and major accidents have now been eliminated for a total of 2 years 9 months, and the number of minor accidents has been steadily decreasing year after year, resulting in excellent operating safety (historically, a high quality level has been 0.85 accidents per hundred cars, while in 1979 the figure was 0.45 accidents).

2. Freight cars. At the end of 1979, the entire system had 4.6 times more freight cars than shortly after Liberation, including an increase of 2.3 times in boxcars and 5.2 times in flatcars. Some 15.9 percent are 30-40 ton cars, and 82.2 percent weigh 50 tons or more. The average nominal weight per car has increased from 32.3 tons shortly after Liberation to 50.6 tons, i.e. by 56.6 ercent. The freight car overhaul rate has increased from 13.5 percent shortly after Liberation to 2.7 percent [as published]. The average accident rate is 0.33 accidents per 10,000 car-kilometers, down by 1.42 accidents from the figure of 1.75 shortly after Liberation, and representing a decrease to 19 percent of the earlier figure.

Repair and Construction of Railroad Rolling Stock

In 1979 the plants of the railroad rolling stock industrial system fulfilled or overfulfilled all of their railroad rolling stock in-plant repair and new construction targets. Output of new electric and steam locomotives and passenger cars and repair of internal combustion locomotives increased over last year. The output for these four areas was a record for the last 20 years (the output of various areas is shown in the table).

The total industrial output value for the year was 1.733 billion yuan, 109.4 percent of the planned figure, and 22.1 percent above the record level of 1975.

In order to meet the needs of modernization of railroad transport, the various plants have also made an energetic effort to develop new products. The Sifang and Puzhen plants developed three different air conditioned passenger-train cars (including a parlor car, a dining car and a generator car) for the Guangzhou-Jiulong passenger route. The cars are 25.5 meters long and use such new technology and materials as a high-speed wheel truck design, a low-alloy unitized load-bearing chassis design without a central beam, and rubber shock absorbers. The Wuchang plant has produced the new model B19 mechanical refrigerator car, whose design has been finalized following ministry-level evaluation, setting the stage for lot production. The Chichihar plant has experimentally developed a 75 ton capacity flatcar and a 450 ton long-bodied car for large items. The Qishuyan plant has produced a grain hopper car. In addition, the Chichihar plant, the Harbin plant and the Xi'an plant have produced various types of narrow gage freight cars (for the Kunming railway).

Repair and Construction of Railroad Rolling Stock in 1979

Product	Actual	Actual as Percentage of Plan
Steam locomotives	2,999	102.2
Internal combustion locomotives	333	104.1
Repair		
Passenger coaches	2,446	101.1
Freight cars	41,686	101.1
Cranes	347	100.6
Steam locomotives	311	103.7
Internal combustion locomotives	222	100.9
Electric locomotives	40	100.0
New construction		
Passenger coaches	856	100.7
Freight cars	16,042	100.8
Cranes	70	100.0

The axle bearing production line imported by the Nankou Rolling Stock Mechnical Plant has already gone into trial production, and has created the conditions for speeding up the equipping of freight cars with ball bearings.

Railway Communications Signals

In 1979, China's railroads already had 9,066 kilometers of long-distance communications cable, accounting for 16.7 percent of all the country's railway signaling lines. There are a total of 170,000 local telephone sets.

A wireless dispatcher's telephone for train operations officially went into trial production in 1975 and had its design finalized; by 1979 there were about 2,071 fixed sets and 4,394 sets on locomotives. Currently, wireless dispatcher telephone equipment is in use on 9,000 kilometers of railroad.

In order to meet the speed and density requirements of various types of transport, the block equipment on Chinese railroads is mainly automated, semiautomated or sign or semaphore type. In 1979 there was a total of 5,997 kilometers of automated block signaling systems and 36,185 kilometers with semiautomated blocking systems. The automated blocking systems are primarily of the frequency-shift, extra-high frequency, and AC counter types. The semiautomated blocking systems are Chinese-produced model 64 continuous-current semiautomated equipment.

To assure traffic safety, to increase traffic efficiency and to bring train marshaling and breaking down capabilities into play, in 1979, 75 electric marshaling yards, 2 mechanical hump marshaling yards and 7 simple hump marshaling yards were constructed. By the end of 1979 the country's railroads had 1,432 marshaling yards; 3 semiautomated hump marshaling yards, 15 mechanical hump marshaling yards, 31 non-mechanical hump marshaling yards and 56 simple hump marshaling yards.

The country has 907 kilometers of dispatching and marshaling facilities, 729 kilometers of which are electrical, while the rest are extra-high frequency types. There are 215 kilometers of dispatcher-overseen track.

Railroad Track

In 1979 China's railroads replaced 2,507 kilometers of track, so that 41 percent of single lines had 50-kilograms per meter. In 1954 Chinese iron and steel enterprises began producing their own steel track, gradually unifying the gage standards. The heaviest steel track is the 60-kilogram type (now beginning to be laid experimentally), followed by the 50-kilogram and 43-kilogram types. Steel track materials include carbon steels, medium-manganese steel and high-silicon steel. Switch designs include models No 9, No 12 and No 18. They include the tandem standard frog, high-manganese cast frog, ordinary curved arm and special-section arm designs.

In 1979, 638 kilometers of seamless track was laid. China started laying seamless track in 1957, and has now laid 7,200 kilometers. The method of welding seamless rail is that in the plant, gas pressure welding or contact welding is used to produce 200-meter or 250-meter rails, which are moved to the project site and welded into 1,000-meter rails with thermite.

In 1979 3.25 million prestressed concrete ties were laid. They were first produced in 1956, and currently 46.34 million have been laid, including 41.23 million on single-track lines, accounting for 45 percent of all those on such lines. All other ties are made of wood; they have been oil treated by domestic treatment plants.

In order to adapt to high traffic densities, track maintenance uses lightweight devices including a small hydraulic tamper, an electrical tamper and hydraulic tools. Large hydraulic tampers and ballast washing sieves are used only when lines are closed for major overhaul.

Highways

Highway Construction and Traffic

Shortly after Liberation, China only had 80,000 kilometers of highway, mostly in the flat or hilly areas of the Southeastern coastal provinces, while mountain areas and border minority areas which account for more than two-thirds of the country's total area had almost no highways.

After New China was founded, 30 years of energetic construction followed, and by the end of 1979 the operating highway mileage had reached 890,000 kilometers. A highway system centered on Beijing which linked the capitals of all the provinces, joined all the harbors and rail centers and reached into the vast countryside was beginning to take shape.

In 1979 total goods transport turnover on the nation's highways was 26.8 billion ton-kilometers, a decrease of 2.2 percent from the 1978 figure of 27.4 billion. This decrease resulted because the industrial and commercial enterprises increased their own hauling capacities and the transport departments' haulage work decreased; but compared with 800 million ton-kilometers in 1949, this was an increase of 33.5 times. Passenger turnover was 60.3 billion passenger-kilometers, an increase of 15.7 percent over the 1978 figure of 52.1 billion, and an increase of 65 times over 1949.

Not only has the number of highways increased rapidly, but their quality and technical condition have also been considerably improved. Shortly after Liberation the vast majority of highways could not meet any classification standard, the roadbeds were low-lying, subject to waterlogging, and narrow, there was a shortage of bridges and culverts, and there were sharp turns and steep slopes. Now, many highways have met the standards for the 4 state classifications. Most trunk highways have attained class 3. Some important trunk highways are being reconstructed to class 2 status. By the end of 1979, there were 143,000 kilometers of asphalt and oiled roads, 454 times the 315 kilometers that existed shortly after Liberation. Class 1 roads are being built on the access routes to large and medium size cities and between large and medium cities. Those which had been built and were in operation in 1979 included the following: The Beijing-Miyun Highway is 39.1 kilometers long, with a roadbed 25 meters wide and a 2-meter-wide median strip, both highway surfaces 10.5 meters wide and a shoulder 1 meter wide. The Shenyang-Fushun Highway is 27 kilometers long and 29 meters wide, with a highway surface 25 meters wide, and has a total of 6 lanes. The Nanjing-Liuhe highway is 24.7 kilometers long and the roadbed is 23 meters wide, with a 1.5 meter median, 10-meter-wide road surfaces and 0.75-meter shoulders. This is a high-speed divided highway. The Nanjing-Liuhe highway is 24.7 kilometers long and the roadbed is 23 meters wide, with a 1.5 meter median, 10-meter-wide road surfaces and 0.75-meter shoulders. This is a high-speed divided highway. The Nanjing-Liuhe highway can carry 17,500 vehicles a day, a capacity more than 2 times greater than older roads. The new road has reflective lane markers for the convenience of vehicles traveling at night. These 3 class 1 highways are the beginning of China's high-speed highway construction.

In the 36 years since the state was founded the roads that have presented the greatest engineering problems have been the Qinghai-Tibet highway and the Sichuan-Tibet highway. The Qinghai-Tibet highway passes from Xining through Chaka, Xiangride and Golmud to Lhasa in Tibet, the "ridgepole of the world," through the Qinghai-Tibet Plateau, with an altitude of over 4,000 meters, and crosses the upper reaches of the Yangtze River and the Kunlun and Tanggula mountain ranges, among others, extending a total of more than 2,100 kilometers. The Sichuan-Tibet Highway passes from Chengdu through Yaan, Ganzi and Manigange to Lhasa, passing over the Erland, Zheduo and Queer Mountains and the Daduhe, Jinshajiang, Lancangjiang and Nujiang rivers. Its average altitude is over 3,000 meters, and it is a total of over 2,400 kilometers in length. These two highways are important lines of communication between Lhasa, the "ridgepole of the world," and China proper, and each of them took 3 or 4 years to construct, presenting engineering difficulties practically unprecedented in world highway building. The road surface of the Qinghai-Tibet highway is being continually upgraded to an oiled surface.

Highway Bridges

By the end of 1979, there were about 128,000 highway bridges in China, with a total length of more than 3 million meters, 93 percent of them permanent bridges. Many major highway bridges have been built over large rivers where bridge building is difficult. More than 30 bridges have been built across the Yellow River, including China's longest highway bridge, the Loyang Yellow River Bridge in Henan, which is 3,429 meters long. In 1979 a 5-span continuous prestressed concrete bridge, the Lanzhou Yellow River bridge, 304 meters long and 21 meters wide, was built at Lanzhou.

Bridge building technology has also been greatly improved. In stone arch bridges, for an example, before Liberation the largest span remained the 37.37 meter span of the Chaozhou Bridge, more than 1,300 years old. Now the longest span of a stone arch bridge is 116 meters. The bridge builders in Wuxi, Jiangsu absorbed into their work of developing stone arch bridges the best aspects of modern bridge design and construction, and developed a new bridge type: the hyperbolic arch bridge.

While energetically developing bridge building technology, we have also actively adopted new foreign bridge building techniques and designs. For example, the Huoshiyan bridge over the Han River at Ankang, completed in 1975, uses a recently-developed design, the oblique tension bridge. The main span is 120 meters long, and is currently the longest oblique tension bridge span. In addition, China's first combined aircraft runway-highway overpass bridge, on the route to the Capital International Airport in the suburbs of Beijing, has a net height of 4.5 meters and a breadth of 60 meters. Atop the bridge are an aircraft runway, a motor vehicle road and a exhaust deflector. It supports 500 tons, and below it are a walkway and fast and slow car lanes separated by cinder block or a green barrier. The lower part consists of inverted-trapezoid thin-walled steel-reinforced concrete piers, while the upper section consists of 10 52-meter-long, 310-ton box-shaped beams. The bridge bears the heaviest load of all bridges in China.

Containerized Highway Transport

The use of motor vehicles to transport containers by road is an important way of utilizing door-to-door transport and realizing the maximum economic benefit from container transport. At present, highway container transport in China is in the initial stage, and is generally used only for shipment between truck terminals, harbors and warehouses. According to statistics, in 1979 rail-highway door-to-door transportation performed by motor vehicles accounted for 13 percent of all railroad container transport. In addition, highway shipping departments in such areas as Shanghai, Tianjin, Heilongjiang, Anhui, Jiangsu and Guangdong have begun various degrees of initial development of direct highway transport of containers. The shipping departments have taken many steps to induce shippers to use containers, such as simplifying consignment procedures to make them more convenient for the shippers, drawing up container pricing methods and standards so that they give the shippers the maximum economic advantage, improving truck facilities to meet container-associated requirements for standardization, series design and the like, and developing a system of priority transport for containers so as to bring vehicle efficiency into play. It is forecast that when the shipping departments extend container transport to distant suburbs from the cities, China's highway container transport will undergo rather considerable development.

Highway Transport of Large and Heavy Items

As science and technology have developed, industrial equipment has tended to become larger and heavier; some individual pieces weigh as much as several dozen tons to several hundred tons, with external dimensions up to several tens of meters. This has greatly exceeded the limits set for highway and transport vehicles. Transporting this equipment without a hitch to construction sites for installation is an extremely complex task. Experience shows that in organizing transport of large or heavy items four problems must be solved: 1. selection of a vehicle and preparation of a loading diagram; 2. choice and improvement of the transport route; 3. determination of the loading and unloading procedure; 4. implementing organizational and technical measures for transport. At present China's transport capabilities for large and heavy items are already respectable. The largest load capacity of a single unit is 600 tons; the greatest-length item that can be transported is over 70 meters long. Special transport bases for large and heavy items have been set up in the Tianjin, Wuhan, Kunming, Cangzhou, Shanghai, Beijing, Chengdu and Shenyang areas. These are capable of transporting large or heavy items on a national scale. According to statistics from motor transport enterprises subordinate to the Ministry of Communications, in 1975-1979 more than 28,600 tons of heavy and large items were carried, including more than 150 items weighing over 80 tons; the largest was 354 tons.

Water Transport

River Transport

In 1979 China had 136,000 kilometers of navigable rivers. The Yangtze, one of the four longest rivers in the world, had about 18,000 kilometers of main stream and tributaries navigable by steamers.

Since the founding of the state, a great deal of work supporting river navigation has been done in the areas of improvement of channels, harbor construction, boat construction, installation of navigational signals and the like. In the past there were so-called "natural barriers" on the upper reaches of the Yangtze. There were four conditions under which navigation was impossible: at high water, at low water, at night and in bad weather. By means of channel improvements and electrification of navigation signals, natural barriers have now become thoroughfares. Before channel improvement the Hanyu [Hankou-Chongqing] passenger steamer took 20 days to make a round trip, while now it requires 8.

At present, oceangoing vessels in the 10,000 ton class can enter the river and moor at river ports. The harbor areas and berths of many river ports have been improved, expanded and mechanized, and new warehouses and waiting rooms have been built for passenger and freight transport, further increasing their throughput capacity. Special routes, special ships and special wharves are provided for commodities to be shipped in large quantities or over long distances, and lot shipment and containerized shipment have been expanded; priority shipment, priority packaging and shipment on arrival have been adopted for agricultural products, thereby increasing transport speed and improving quality, so that transportation keeps pace with the agricultural seasons. In recent years, the advanced transport method of sectional pushed barge transport has been greatly expanded. Some 300,000 tons of 300-ton to 1,000-ton sectional barges are operating on the country's rivers; the largest pusher tugs are 4,000 horsepower models which can push 12,000-15,000 tons of goods at one time.

As river transport has expanded, the number of steamers and barges operating on rivers of various sizes has increased by more than 10 times from the immediate post-Liberation figure. Most of these boats were built here after Liberation. At present, there are almost 800 plants serving transport along the main Yangtze River routes alone; these are capable of designing and producing 4,000 horsepower tugs.

In 1979, river transport carried 320 million tons of goods, an increase of 11 times over the immediate post-Liberation figure.

Coastal Transport

China has 18,000 kilometers of continental coastline, several thousand sea islands and many excellent ice-free harbors. In the 30 years since Liberation, China's coastal transport has expended greatly, and the amount of goods carried has doubled and redoubled. In 1979 coastal transport carried 68 million tons of goods and performed 45.6 billion ton-kilometers of transport work, primarily carrying coal, petroleum and iron ore.

China's coastal transport is centered on Luda, Shanghai and Guangzhou. All coastal ports can be reached from these locations. The most important coastal transport enterprises include the Shanghai Marine Transport Bureau and the Guangzhou Marine Transport Bureau, which primarily are responsible for long-range internal and coastal goods and passenger transport. The Shanghai Marine Transport Bureau carries more than 36 million tons of freight annually. The Guangzhou Marine Transport Bureau carries more than 13 million tons a year. In addition, the coastal provinces have their own marine transport bureaus, which primarily deal with intraprovince coastal transport. New routes opened in 1979 included Shanghai-Hong Kong, Guangzhou-Hong Kong and Amoy-Hong Kong.

Ocean Transport

China's ocean transport is carried out by the China Marine Transport Corporation, located in Beijing. The corporation has branch offices in Shanghai, Guangzhou, Qingdao, Tianjin and Dalian. In addition, there are companies run jointly with other countries, such as the China-Poland Marine Transport Company, the China-Tanzania Joint Transport Company, the China-Sri Lanka Joint Marine Transport Line and the like, as well as the People's Republic of China Business Agency in Hong Kong.

In all the areas where the transport companies are located and in the main harbors there are also such training and support organizations as seamen's schools, crew bases, seamen's hospitals and ship supply stations, which directly support ship personnel's transport work and the sailor's daily livelihood.

By 1979 China had constructed an ocean-going transport fleet consisting of more than 400 bulk cargo ships, miscellaneous cargo ships, tankers, passenger ships, liquid cargo ships and container ships with a capacity of more than 7 million tons. This fleet has become the main force for foreign trade, and has fundamentally altered the past situation of relying primarily on rental of foreign vessels.

China's marine routes originate in Shanghai, Guangzhou, Qingdao, Tianjin, and Dalian. There are four main routes:

The eastern route, from the major coastal ports east to Japan, and across the Pacific to Canada, the United States and Latin America;

The western route, from the major coastal ports westward through the Indian Ocean, the Suez Canal, the Mediterranean to the Atlantic, or south around the Cape of Good Hope into the Atlantic, with stops at ports in various countries of South Asia, Africa and Europe;

The southern route, from the major coastal ports southward to the countries of Southeast Asia and Oceania;

The northern route, from the various coastal ports north to Korea and the east coast ports of the Soviet Union.

In 1961 China's maritime vessels stopped only at 13 ports in 5 countries. By 1979, they were stopping at more than 400 ports in more than 100 countries and regions.

Some of China's maritime transport vessels were bought abroad and some were built in China. In 1968, China used imported materials and equipment to assemble the 10,000 ton freighter Yuejin, and in 1965 by its own efforts it produced the 10,000-ton steamer Dongfeng. By 1979, China had already constructed a 25,000-ton freighter, a 7,500-ton passenger ship and freighter, and a 50,000-ton tanker, which helped China in foreign trade and the import of large-sized manufacturing equipment and badly-needed commodities.

Construction of Coastal Ports

Coastal ports are important nodes in the connection between land and water transport and important thoroughfares by which domestic and foreign commodities are exchanged. There are 15 major harbors on China's extensive coastline, and in 1972 their handling capacity was about 100 million tons. With the steady increase in foreign trade and the steady development of the domestic economy, the original port facilities and capabilities became inadequate for the needs of the developing situation. In 1973 the state decided to expand port cargo handling facilities, and after several years' effort it completed construction of a group of bulk cargo and miscellaneous cargo wharves, making a considerable change in the appearance of the ports. Originally the only crude oil facilities where Dalian's facilities for 20,000-ton vessels, which had very small capacity. There are now 4 ports with moorings for 100,000, 50,000 and 20,000 ton tankers. The annual petroleum transport capacity can be as high as 41 million tons. The coal and miscellaneous cargo docks' handling capacities have also been rather considerably increased. Container docks are being built at the Tianjin, Shanghai and Huangpu harbors, and will soon be in operation.

In 1979, 42 10,000-ton or higher larger deep-water moorages had been built in China's 15 coastal ports, so that their handling capacity was up 66 percent over the 1973 figure and 22 times greater than shortly after Liberation. In 1979, 212.57 million tons of cargo was handled, up 6 percent from the 1978 figure. At the same time, 150 production lines have been opened at old wharves, and the passenger facilities and fuel and water supply facilities have also been modernized.

Aviation

The Development of China's Civil Aviation

After 30 years of development, by 1979 Chinese civil aviation already had 173 routes, including 158 domestic routes and 15 international routes. The total length of all air routes, eliminating duplication, is 159,971 kilometers, including 108,658 kilometers in domestic routes and 51,313 kilometers in international routes.

More than 80 cities are on the domestic routes. Chinese civil aviation's production equipment is being gradually modernized, and currently with the exception of medium and small aircraft used for industrial and agricultural aviation work (such as aerial surveys, mineral prospecting, insect control, seeding, weed eradication, fertilizer application, forest protection, sea rescue and the like), the primary aircraft used in air transport are the AN-24, AN-12, Viscount, Il-18, Trident, Il-62 and Boeing 707. To meet the needs of expanding tourism and the opening of new international routes, in 1979 3 Boeing 747SP wide-bodied jets were imported, officially entering scheduled service in 1980. These aircraft can carry 291 passengers, have an average speed of 950 kilometers per hour and can fly nonstop for about 15 hours.

In the last 30 years, Chinese civil aviation's carrying capacities have developed at a rate of 20.65 percent a year. In 1979, total transport turnover was 380 million ton-kilometers, up 26 percent over 1978; passenger transport amounted to 2.93 million passengers, up 26 percent over 1978; parcel post capacity was 77,000 tons, up 22 percent over 1978. Specialized aviation logged 39,700 hours, up 37 percent from 1978.

In 1979 17 new routes were opened, including 3 international and 14 domestic routes.

The three newly-opened international routes are: Beijing-Guangzhou-Manila, Beijing-Tehran-Bucharest-Frankfurt and Beijing-Shanghai-Nagasaki.

The 14 new domestic lines are: Guangzhou-Fuzhou, Guangzhou-Xingning, Xi'an-Lhasa, Shanghai-Hefei-Wuhan, Urumchi-Ku'erle-Qiemo, Shanghai-Wuhan-Chengdu, Shanghai-Chongqing, Tianjin-Nanjing-Guangzhou, Tianjin-Shanghai, Chengdu-Guangzhou, Beijing-Wuhan-Guiyang, Beijing-Wuhan-Nanning, Wuhan-Xi'an and Beijing-Harbin.

According to preliminary plans for Chinese tourism, in 1983 the number of foreign tourists entering the country will be 1 million, and by 1985 the figure will increase to 3-3.5 million. This is a forecast for a rather large expansion of China's civil aviation, requiring the provision of even greater transport capacities. It is forecast that by 1985 total transport turnover will increase to 0.8-1 billion ton-kilometers, while at the same time the number of passengers carried will increase to 7-10 million.

China's Largest Modern Airport: the Capital International Airport

The Capital International Airport is located in Shunyi County, in Beijing's northeastern suburbs, 25.2 kilometers from Tian'anmen in the center of the city. This airport was put into operation in 1958. Its original runway (the east runway) was 3,200 meters long, 60 meters wide and 25 centimeters thick; the waiting terminal had an area of 10,711 square meters. In order to meet the needs of international traffic and to accommodate large aircraft, in 1974 expansion was undertaken. The new expanded runway and terminal were officially put into operation on New Year's Day 1980.

The runway built during the expansion (the west runway) is 3,200 meters long, 50 meters wide and 38 centimeters thick and can support 400 tons; it can be used by the world's largest aircraft, such as the Boeing 747, the DC-10 and the Concorde.

The new terminal includes a main terminal building and two satellite buildings connected to it by arcades. Each of the satellite buildings has 8 stations to accommodate the large and medium sized aircraft. The terminal was designed to accommodate 1,500 travelers at peak periods, and has a total space of 59,500 square meters. The parking lot can accommodate 400 automobiles. In order to provide for future expansion of passenger accommodations, space for an additional satellite building has been reserved west of the terminal. In addition, a little way to the south of the terminal is a 12,750-square-meter guest house with 300 beds.

The new terminal has five floors, including a basement and the equipment floor, and arriving and departing passengers use different levels.

There are private entrances for distinguished visitors at each end of the terminal on the first floor, including a VIP lounge and various special facilities. The first and second floors also have group lounges and boarding lounges. On the south side of the east end of the first story are the foreign airlines' offices. Travelers service facilities in the terminal include: telegraph, telephone, postal facilities, banking, automobile rental, baggage checking, information, broadcast, arrival and departure information and baggage transport display systems, and various guide facilities. Transport support facilities include: closed circuit television, teletypewriter, dispatcher telephone and loudspeaker communication.

The new terminal has an in-situ poured concrete framework, steel roof trusses and a raft-type foundation and is designed to withstand an earthquake of magnitude 8. The decoration of the building aims at simplicity and light, and has allowed for thermal insulation and sound absorption. The external walls and the main hall use traditional Chinese construction techniques and have murals rich in national flavor, as well as such artistic adornments as lacquer and colored ink pictures. In addition, new building materials have been used. Building facilities include air conditioning, heating, liquid petroleum gas, fire protection, running water, sewage, hot water and lighting systems.

The expansion of the capital airport is still under way. In 1980 it is planned to complete conversion of the original east runway into the main runway by extending it to 3,800 meters and increasing its thickness to 42 centimeters; at the same time, a major effort is being made to complete the construction of the new tower for the flight control and dispatching center and the like.

Developing Tourist Charter Aviation

In order to develop tourism, Chinese civil aviation has actively promoted tourist charter flights. On the basis of incomplete statistics, in 1979 China's civil aviation organizations carried out 2,500 tourist charter and international charter flights. The tourist charter routes include routes from Europe to Beijing, from Japan to Shanghai and Beijing, and from Hong Kong to Beijing, Guangzhou, Shanghai, Hangzhou, Nanjing, Guilin and Kunming. In order to transport tourists to the Beidaihe River and Changde, special Beijing-Beidaihe and Beijing-Chengde unscheduled tourist charter routes have been opened. The relevant departments of the Shanghai Civil Aviation Management Office and the Shanghai Travel Agency have operated various tourist charter and extra flights; in 1979 they arranged a total of over 180 tourist charter flights, carrying more than 22,800 Chinese and foreign passengers. Tourist packages, including 8-day and 10-day trips from Hong Kong to Nanjing and Hong Kong to Hangzhou, 3-day trips from Shanghai to Guilin, 1-day trips from Shanghai to Beijing and honeymoon trips from Shanghai to Nanjing have been arranged, in addition to which many tourist charters for foreign visitors, overseas Chinese and residents of Hong Kong and Amoy from Shanghai to Beijing, Guangzhou, Guilin, Qingdao and Hangzhou have been organized. The Guangzhou Civil Aviation Management Office organized 84 tourist charter flights from Hong Kong to Guangzhou, Guilin and Kunming and elsewhere between 20 September 1979 and the end of the year.

Goods Turnover of China's Modern Transport Facilities
(hundreds of millions of ton-kilometers)

Type	1949	1952	1978	1979

* The highway transport figure refers to transport by the Ministry of Communications and does not include transport by the industrial enterprises.

Posts and Telecommunications

Historical Survey of China's Posts and Telecommunications

The people's postal services in China began during the revolutionary war. In 1928, in the Jinggangshan Revolutionary Base Area, the Xianggan Border Workers and Peasants Democratic Government formally established the "Red Post Office," serving workers, peasants and soldiers, and in 1929 issued stamps depicting a red star and a sickle and axe. During the first reactionary "bandit encirclement" struggle Red Army fighters captured a 15-watt radio station and set up a wireless brigade. The birth of the "Red Post Office" in the Jinggangshan Revolutionary Base Area and the formation of the Red Army's wireless brigade marked the Chinese people's acquisition of their own post and telecommunications operations; this was the beginning of a new chapter in the history of Chinese posts and telecommunications.

In 1 November 1949, the Ministry of Posts and Telecommunications of the Chinese People's Republic was formally established, to centrally manage and administer the nation's posts and telecommunications activity; during the 3 years' recovery and the subsequent work of development and construction, it developed into a posts and telecommunications network centered on Beijing and reaching out into the vast countryside. Posts and telecommunications serve as an important component of the social productive forces and are playing an increasingly important role in socialist construction and the people's livelihood.

In 1979 the country had 49,647 posts and telecommunications bureaus and offices, 1.9 times as many as in 1949; there were a total of 791,189 posts and telecommunications personnel, 7.7 times more than in 1949; the total business done by posts and telecommunications was 1,255.46 million yuan, 12.9 times more than in 1949.

Posts

In 1979, the total length of postal routes throughout the country was 4,812,271 kilometers, including 161,610 kilometers of air postal routes, 148,876 kilometers of railroad postal routes and 574,732 kilometers of motor postal routes. A total of 99.8 percent of rural people's communes and 96.9 percent of production brigades were on postal routes.

In 1979 the posts handled 3,079,000 letters, 15,919,000 documents and 70,746,000 parcels. The number of periodical issues carried was 126,804,000. The total number of copies of periodicals issued was 16,069,059,000.

Postal codes. In January 1981 the Ministry of Posts and Telecommunications held a conference and decided that starting on 1 July 1980 a nationwide postal code system would be instituted. The postal codes are based on the routes taken by letters and on the delivery areas. The country's several tens of thousands of posts and telecommunications bureaus and offices are each assigned a 6-digit number in Arabic numerals, the postal code. In this 6-digit number, the first 2 digits indicate the province, municipality or autonomous region, the third digit gives the postal region, the fourth gives the county or city, and the last 2 digits give the delivery office and its delivery area. The implementation of the postal code system creates the conditions for using machinery to sort letters and for gradually developing a modern posts and telecommunications network, makes manual sorting simpler, decreases handling time and makes mail delivery faster and more accurate.

Postage Stamps. China's postage stamps are issued by the Ministry of Posts and Telecommunications. They are divided into ordinary stamps, commemorative stamps and special stamps. Ordinary stamps are for general use. Commemorative stamps are issued to commemorate some historical event or outstanding or heroic person. Special stamps are used to propagandize some valuable or significant event. In the period immediately after Liberation, postage due and airmail stamps were issued.

China's first postage stamps were issued in 1865 by the chancery of the Ministry of Works in the Shanghai concession. In 1878 the Shanghai Customs Office issued the Qing Dynasty government's first postage stamp, which bore the image of a dragon's head, and the stamps were accordingly called "dragon heads."

In 1928 the Xianggan Border District Worker-Peasant Democratic Government in the Jinggangshan Revolutionary Base Area established the "Red Post Office," and in 1929 it issued the first postage stamps, bearing a red star and a sickle and axe.

In 1979 the Ministry of Posts and Telecommunications issued 83 varieties of stamps in 26 sets. Of these, there were 32 varieties of commemorative stamps in 15 sets and 4 small-size stamps in 4 sets; 50 varieties of special stamps in 10 sets and 4 small-size varieties in 3 sets were issued; and there was 1 issue of 1 variety of ordinary stamp.

Between 1949 and 1979, a total of 1,606 stamp varieties in 386 sets were issued.

Telecommunications

In 1979 China was operating the following main telecommunications services: telegraph (including public telegraph and telex), telephone (including long distance telephone, long distance conference telephone, urban telephone and rural telephone), and facsimile (including photograph transmission and facsimile). In addition it was in charge of broadcasting radio and television programs.

The quantities of telecommunications work in 1979 were as follows: 134,950,000 telegrams sent, 54,000 facsimiles, 205,869,000 long distance telephone calls, 1,270,160 urban telephone sets in operation by the end of the year, 762,842 rural telephone sets in operation by the end of the year.

Currently, China has 711,925 kilometers of long distance open-wire equipment and 29,092 long distance voice channels.

China started constructing microwave trunk lines in 1969, and now has more than 14,500 kilometers of these lines; 960-channel and 600-channel microwave links connect 26 provinces, municipalities and autonomous regions, and transmit telegrams, telephone messages, facsimile, and television and radio programs. Newspaper facsimile service has been instituted between Beijing and 9 cities including Chengdu, Guangzhou and Nanning.

China's first 1,800-channel coaxial cable, the Jinghuhang [Beijing-Shanghai-Hangzhou] coaxial cable carrier-wave project, was begun in October 1973. Now circuits are open between Beijing, Tianjin, Shijiazhuang, Jinan, Hefei, Nanjing, Shanghai and Hangzhou. This equipment has been used to initiate automatic and semiautomatic long distance dialing.

The country's urban telephone exchange capacity is 1,852,470 circults, including 1,161,630 automated telephone exchange circuits. On average, there are 0.4 telephones per hundred inhabitants.

The Beijing Telegraph Building is China's domestic and international telecommunications center; it forms a national telegraph communications network centered on Beijing and connecting all of the provinces, municipalities, autonomous regions, areas or cities, and counties. It primarily uses electrical cables, short wave, microwave and satellite transmission methods to transmit public telegraph, telex, facsimile, newspaper facsimile, and data link communications.

In recent years, because of the rapid development of telex, the telegraph building has adopted domestically-produced electronic fully automated telex exchanges, thereby further developing China's telegraph services.

The Beijing Long-Distance Telephone Building is the center of China's domestic and international long distance telephone communications. It contains 1,800-channel coaxial carrier wave equipment, 960-channel microwave equipment, coded distribution frame long distance automatic telephone exchanges, simple cordless long-distance telephone exchange consoles and image transmission equipment. This equipment was all developed by the scientific and technical personnel and workers of the China Posts and Telecommunications system with the support of its brother departments. The use of this new equipment has made available important communications capabilities, and has made telecommunications service more intensive and extensive, as well as providing some foundation for future implementation of large-channel-based communications equipment.

International Communications

China has established direct postal relations with 100 countries and areas, and has established circuits to 47 countries and areas.

Three communications satellite ground stations in Beijing and Shanghai maintain direct satellite voice channels with 27 countries via international communications satellites over the Indian and Pacific Oceans.

In addition, an undersea cable has been laid between China and Japan. It has a capacity 480 channels and was officially put into operation on 25 October 1976.

China's Relations with International Postal and Telecommunications Organizations

On 13 April 1972 China recovered its lawful rights in the International Postal Union. China is currently a member of the Executive Council and Advisory Council of the organization.

On 29 May 1972, China regained its legal rights in the International Telecommunications Union. Currently it is a member of that organization's executive committee.

On 17 November 1975 China joined the Asia-Oceania Postal Union, and participated in its Third Conference and in all executive and consultative conferences since 1976.

The International Telecommunications Satellite Organization is a commercial organization of national governments aimed at developing global satellite communications. In August 1977 China formally joined this organization.

The Asia-Oceania Regional Telecommunications Organization was formally established on 8 May 1979. On 25 October 1976 China signed the charter and formally joined the organization.

FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

REFORM OF SICHUAN BANKING SYSTEM DESCRIBED

Beijing ZHONGGUO JINRONG /CHINA'S FINANCE7 in Chinese No 6, 1981 pp 16-18

/Article on Sichuan Branch of the People's Bank of China: "Practice and Knowledge of Sichuan's Banking Reform"7

/Text7 A restructuring of the system of Sichuan People's Bank organizations was gradually carried out in the course of implementing the policy of readjustment rectification and improvement of the national economy during 1980.

Along with the readjustment, restructuring and development of the national economy, banking operations were confronted with many new situations and new problems, with which our existing banking system and methods were incompatible. In the winter of 1979, leading comrades of the provincial party committee discussed with the bank many times the necessity of restructuring the banking system. In accordance with the decision of the provincial party committee and the headquarters of the people's bank, the people's bank organizations in Sichuan began experimenting with restructuring the system. They took reform of the banking system and the readjustment of the national economy as the central tasks and actively launched this work. It is necessary to look back on the practice of restructuring the banking system over the past year to search for patterns so as to bring into play the regulatory role of the bank in readjusting the national economy and in promoting readjustment and development of the national economy.

The reform of Sichuan's banking system during 1980 had the following features: expansion of credit service and start of intermediate and short-term equipment loans to help enterprises tap their latent power and carry out innovations and transformations; reform of the credit planning and management system and implementation of the "centralized planning, decentralized management, linkage of loans to deposits, and control over balance" measures so as to organize funds and use funds more efficiently; change in the fund control system of unified receipt and payment, introduction of business accounting, and trial implementation of measures such as retention of a share of profits, underwriting of costs, and reward according to points recorded, so as to bring the enthusiasm of the banks and their staff into play. The practice over the past year has shown that this experimental reform was in the right direction, it is a road that can be taken; the steps were steady and the results were good; the reform played an active part in bringing the role of banks into play, regulating social production and accelerating economic readjustment; and it was well received by party and government organs and enterprises in all localities.

Initial Results of Reform

The reform of the banking system achieved initial results quickly. Deposits with the bank organizations in the province grew, loans were flexibly utilized, the turnover of funds was accelerated, the quality of work improved, the banks' profits increased, and the reform played an active role in the readjustment and development of the national economy. The main results may be summarized in three aspects:

I. Strengthening the Banks' Regulatory Role, Accelerating the Readjustment and Development of the National Economy

The start of intermediate and short-term equipment loan service was a major reform as well as an important link in strengthening the banks' regulatory role. The people's banks in Sichuan arranged 1,590 projects financed by intermediate and short-term equipment loans and granted loans totalling 388 million yuan during 1980. By the end of last year, 807 projects had been completed and put into operation, thereby increasing the output value by 382 million yuan, and 63 million yuan in loans had been recalled. The remaining projects are expected to go into operation during 1981. On the basis of the economic results estimated item by item, each 100 yuan in loans can increase output value by 298 yuan and increase tax and profits by 64 yuan. Compared with the allocation of funds to build plants, equipment loans take a shorter time, get quick returns and achieve greater gain and better economic results.

The principle of "dealing with each case on its merits and aiding the good" was another important link in strengthening the banks' regulatory role. In 1980, the people's banks in Sichuan moved from the selection of good enterprises to the selection of good products. Taking "meet the needs and produce good-quality, low-cost products" as the standard, in granting loans the banks gave priority to products of good quality and in great demand, aided products that were in short supply, restricted products that were in excessive supply and urged enterprises to produce according to needs. The banks tightened control over loans to finance production of inferior quality and unsalable products, and promoted adjustment and change of products.

II. Arousing the Enthusiasm of Banks for Raising and Utilizing Funds, Improving Fund Management

After implementation of the system of planned management of credit loans--"centralized planning, decentralized management, linkage of loans to deposits, and control over balance"--the banks acquired the power to make unified fund arrangements, to lend more against more deposits, and to regulate loan projects. This plus the direct linkage of deposit and loan service results to retention of a share of profits and bonuses for the staff brought into play the enthusiasm of banks for organizing funds and utilizing funds and improved fund management.

After reform of the banking system, the attitude of attaching no importance to deposits was changed, the banks began to organize deposits as their main line and gained a firm grasp of three aspects: 1)organizing savings; 2) organizing deposits by industrial and commercial enterprises; and 3) organizing deposits of small amounts of money.

After reform of the banking system, the banks made flexible use of funds. They could regulate the targets of industrial and commercial loans by themselves and could use the earmarked funds (transferred from the higher authorities for intermediate and short-term equipment loans) to meet the short-term needs of other enterprises to take their latent power and carry out innovations and transformations. Because of this and also because of the vast number of credit work personnel who went to enterprises to help them improve their operation and management and strengthen their business accounting, the turnover of credit funds was speeded up. In 1978, industrial and commercial credit funds turned over 4.95 times; the turnover was speeded up 0.96 times during 1980. With the turnover of funds speeded up, the saving of funds reached 1.59 billion yuan.

III. Increasing Banks' Internal Economic Dynamics, Promoting Fulfillment of Various Economic Targets

Formerly, the people's banks followed the practice of "eating from the same pot"--unified receipts and payments. The banks' operations and the bank staff's contributions were not linked to the interests of units and individuals, and the principle of material benefits was overlooked. Now, business accounting has been strengthened; retention of a share of profits and underwriting of costs has been tried out; the interests of the state, units and individuals have been combined; power, responsibility and interests have been combined; and retention of a share of profits and reward according to points recorded have been linked to fulfillment of economic targets. These measures increased the banks' internal economic dynamics and aroused the enthusiasm of the bank staff. This found primary expression in three aspects: 1) Widespread interest in the results of bank operations. Credit personnel became interested in both loans and deposits. Accountants became interested in both internal accounting and external use of funds. Even personnel officers, general service personnel and cooks became interested in the way the economic targets of their units were fulfilled. 2) Greater initiative in work, higher attendance rate and efficiency, and better quality of work. In the past, some staff members were unwilling to serve behind busy counters. Now, they began vying with one another to carry the heavy load. In the past, some units used to complain about too much to do and too few employees and they wanted additional personnel. Now, they insist that less personnel do more work. 3) More diligent study. In their spare hours a vast number of staff members have learned a trade from veteran workers, attended evening schools for workers, attended lectures, drilled at posts, and have taken part in periodic tests. In these ways they have studied basic theories, and dug into professional techniques, thereby raising their professional level.

Several Points Learned in Practice

In order to insure that reform of the banking system conforms to and promotes the readjustment and restructuring of the national economy, it is imperative to solve the following problems:

I. Know the correct aim of reform and maintain the reform criteria.

Banks are a comprehensive branch of the national economy and an important lever to regulate the social economy. Reform of the banking system should be centered on the economic results achieved internally by the banks and, more importantly, on their economic effects on society. Thus, reform is the means to the end of gradually operating banks in economic ways and arousing workers' enthusiasm so that the bank activity is made more flexible and the role of banks as a lever is brought into fuller play, thereby promoting readjustment of the national economy and the proportionate development of various branches of the national economy. On the basis of correctly knowing the aim of reform, six criteria should be set to measure the results of reform: 1) whether more funds are accumulated than in the past; 2) whether funds are used more flexibly than in the past; 3) whether the economic results of loans are better than in the past; 4) whether successful experience has been acquired; 5) whether the level of bank management is raised; and 6) whether personnel are trained. In the process of reform, the aim and criteria of reform were repeatedly emphasized and adhered to from beginning to end. As a result, the reform made smooth progress in the correct direction.

II. Overall point of view, overall balance.

Bank work involves many aspects and closely follows policy. It is important to adopt an overall point of view and pay attention to overall balance. For example, to grant intermediate and short-term equipment loans, it is necessary to adopt an overall point of view, uphold the readjustment policy, maintain direction over loans, and insure an overall balance. Provided we adopt an overall point of view, pay attention to overall balance, obtain the necessary information, and strengthen investigation and research, we will be able to avoid blindly granting loans and to achieve good results.

III. Strengthen unified leadership, bring the role of the whole into play.

After reform of the banking system, the power of basic-level banks to make unified arrangement and use of funds has been expanded, making it necessary for the banks at various levels to become independent operating units. In view of this, many banks have set up fund control groups composed of planning, credit, accounting, and savings departments under the concrete leadership of the bank presidents. At the same time, they have instituted some essential systems of management such as fund analysis and control; business accounting, registration and examination; management of large depositors; and cutting expenses. The role of the bank as a whole has been strengthened by unified operations under the bank president and the coordinated activities of specialized departments. The presidents of many banks preside over fund analysis and control meetings and business accounting meetings monthly and every 10 days, respectively, to check up on how funds have been raised and used and how various economic targets have been fulfilled, and to arrange work promptly to solve problems. The president of a bank said with deep feeling: "I have been a bank president for more than 20 years, but I am just now beginning to go over reports, calculate the money supply and analyze fund changes every month and every 10 days. The reform of the banking system has 'forced' me to do it." The presidents of some banks said: "The responsibility of a bank president is now heavy but he has greater power, making it easy for him to work and direct operations." These gratifying changes show that many administrative cadres at banks are advancing along the road to operating banks properly.

Continued Reform Called For

The economic structure of our country is irrational to a severe degree and proportionate relations are thrown into a severe imbalance. This is an outstanding problem calling for urgent solution in our economic life. For this reason, in implementing the eight-character policy in our national economy, we must begin with readjustment and carry out reform centered on readjustment, reform that is subordinate and conducive to readjustment. The pressing matter of the moment confronting banking departments is to strengthen credit management and exercise strict control over money put into circulation so as to insure the smooth progress of economic readjustment.

But, readjustment and reform affect each other and promote each other. Coordination of proportionate relations is the prerequisite for overall reform, while success in certain essential reforms will bring grist to the mill of economic readjustment. Therefore, we should continue to uphold the reforms that have been found effective and consolidate and develop the gains of the reforms. Experiments on new reforms that are essential should be systematically carried out under leadership.

First, we should go a step further and improve our handling of intermediate and short-term equipment loans. The fundamental way out for the Chinese economy is to traverwe a new road of improving economic results. This makes it imperative to tap the latent power of existing enterprises vigorously, develop production of consumer goods energetically and carry out overall reform of the structure of the national economy, centering on production of consumer goods. Banks should grant intermediate and short-term equipment loans mainly to aid production of consumer goods for daily use, to help existing enterprises tap their latent power and carry out innovations and transformations and, in particular, to supply the needs of major cities and to insure the funds necessary for production of products in short supply. When granting loans, we should pay serious attention to economic results and speed up fund turnover. Vigorous support should be given to projects that need less investment, get quick returns and achieve big results, or projects that can produce economic results in 1 or 2 years; after determining the purpose of the loans, we should pay serious attention to the speed and operation of the projects, to increasing income and repayment of loans, and strive to improve the effective use of funds.

Second, in granting all types of loans, we should observe the principle of "dealing with each case on its merits and aiding the good." With a view to placing our economy on a new road of improving economic results, banks granting loans must change the former system of supplying funds and aid the good and restrict the bad. The difference in good and bad should be distinguished by industry, by enterprise, and by product, and it is essential to determine the direction in which loans are used according to the standards of salability, good quality and low costs. Vigorous aid should be given to the promotion and development of good-quality and low-cost products that are in great demand. There should be strict control of loans for products that are of inferior quality, high cost, and do not have a ready market. Adjustment of these products should be pushed. By carrying out this reform successfully banks will be able to bring into fuller play their regulatory role in order to aid end products, cut down on intermediate products and uphold the aim of socialist production.

Third, reform of bank management systems such as planned management of credit lines, business accounting, retention of a share of profits, and underwriting of costs should be continued and improved. To meet the requirements of controlling the money put into circulation and promoting economic readjustment, banks should work out annual and biannual plans for bank credit loans and cash receipt and payment. Banks are required strictly to fulfill the targets of underwriting the credit balance and the targets of intermediate and short-term equipment loans without breaking through them. In order to place business accounting on a more scientific basis, banks have changed the method of computing interest on inter-bank funds from the former practice of computing interest on deposits or borrowed funds to one of computing interest on balance in inter-bank accounts; at the same time, banks have appropriately adjusted the targets of business accounting and examination.

Fourth, bonus management should be strengthened. Reward measures should be enforced according to the requirement of economic readjustment and the unified provisions made by the State Council and the provincial people's government. Bonus lines may not go beyond these provisions. Bonuses for units and individuals should be linked respectively to the way the economic targets have been achieved and the way tasks have been fulfilled. Last year, the people's banks in Sichuan put into effect the practice of rewarding according to points recorded, and the provincial branch of the people's bank ruled that those organizations that did not follow this regulation would be given no bonuses. This system played an active part in implementing the "more pay for more work" principle and preventing egalitarianism. We should continue to uphold, consolidate and improve this system.

CONTROLLING MONEY IN CIRCULATION NECESSARY TO READJUSTMENT

Beijing ZHONGGUO JINRONG /CHINA'S FINANCE7 in Chinese No 6, 1981 pp 5-6

/Article by ZHONGGUO JINRONG commentator: "Controlling Money in Circulation in the New Direction of the National Economy"7

/Text7 The recent conference held by the People's Bank to analyze the nationwide circulation of money, in the spirit of the central work conference and on the basis of analyzing the national economic situation and the circulation of money, proposed that to control the money in circulation we should adhere to the principle of withdrawing money from circulation on the one hand and carefully stimulating the economy on the other. We must continue to tighten control where strict control is called for, and resolutely stimulate what should be stimulated. We should keep a constant watch on the market and be aware of the tightness or ease of money on the market at all times. This is an effective measure for tightening control over the money in circulation as well as an important guiding thought we should follow in our work. It conforms to the requirements of the policy of economic readjustment and to the objective law that circulation of money must be suited to the development of commodity production and commodity circulation.

In the readjustment of our national economy, we should on the one hand cut down on capital construction and expenditure and strive basically for financial balance, credit balance and a stable economy; on the other hand, we should go a step further and adjust the economic structure and improve the economic results on the basis of a stable economy. Our economic readjustment is aimed not only at overcoming our present difficulties and eliminating latent dangers but also at opening a new road of economic development that is suited to the national conditions of China. Traversing this new road, we can achieve coordinated development and steady growth of the economy and create a prosperous cycle in which the people can gain more tangible benefits and bring the superiority of socialism into full play. In accordance with the requirements of economic readjustment, the circulation of money should be controlled in such a way that money put into circulation is brought under strict control, withdrawal of money from circulation is vigorously organized, credit loans are balanced and monetary stability is ensured, and the economy is further stimulated by fully utilizing the economic levers of credit loans and interest rates and by properly regulating the money supply on the market. To solve the problems of imbalance in the national economy, financial deficits and rising prices, it is absolutely essential to tighten control over credit loans and money in circulation, and we should persistently undertake this task. But we should not simply pursue the "tight control" cycle. Our fundamental way out still lies in developing production, adjusting the economic structure and improving economic results. Therefore, simultaneously with cutting down on capital construction and expenditure, we must vigorously support and develop the light and textile industries in order to increase production of consumer goods; give support to the needs centered on production of consumer goods, reorganize the entire industrial structure and promote reorganization and combination of enterprises; and give support to development of tertiary industries. By doing this, on the basis of developing production and expanding circulation, we can create adequate conditions for withdrawing money from circulation and on the new road of economic development discover new ways to tighten control over money in circulation. Thus, continuing to tighten control over money in circulation while stimulating economic growth does not mean that our tasks will be light but that they will be heavier and our work will be more complicated and difficult, making it necessary for us to redouble our efforts in order to accomplish them.

Some people argue: "If you want to tighten control, you can't stimulate the economy; if you want to stimulate the economy, you must loosen control." This shows that not all comrades have a correct understanding of the relationship between "control" and "stimulation." The contradictory aspects of all things lie in the dielectical unity of opposites. They are indispensable to each other and complement each other. But some comrades are accustomed to thinking in absolute terms. When it comes to "control," they always try to keep things under rigid control, giving little thought to the consequences that follow from an excessively tight money supply. When it comes to "stimulation" they think that all the measures for control can be eased or that breaches can be made at will. It should be understood that control and stimulation are absolutely not antagonistic to each other. The withdrawal of money from circulation in the first quarter was satisfactory. On the one hand, this was the result of balancing financial income and expenditure, balancing credit loans, and cutting expenditures; this was the effect of "control." On the other hand, it was the result of implementing the party's policies on stimulating the growth of the economy, agriculture, the light and textile industries; this was the gain from "stimulation." In our opinion, we should resort to control or stimulation as occasion demands. We must tighten control where tight control is called for, and we must stimulate what should be stimulated. For example, banks must tighten control and supervision over capital spending, administrative expenses, the "four continues," arbitrary expansion of negotiated purchases, raising of negotiated purchase prices, and financial squeeze and misappropriation of credit funds. Banks should vigorously support the development of agricultural production and production of consumer goods and sideline products; they should support the commercial departments in purchasing agricultural and sideline products that are suitable and in demand and in expanding sales and clearing overstocked goods, and in such cases our control measures should be somewhat flexible. Only strict control can achieve credit balance, satisfy the normal needs for construction funds, and stimulate the economy. With the economy stimulated and a prosperous cycle brought about, sources of credit loans can become abundant and the material foundation can be reinforced for withdrawing money from circulation. It should be understood that "stimulation" does not amount to "loosening of control," and that we should give support to stimulation of the economy and on no account can we loosen control. Control and stimulation are two aspects of management. The more it is necessary to stimulate the economy, the more it is necessary to tighten control. Control and stimulation should be appropriate and in balance.

Some people say: "Withdrawal of money from circulation in the first quarter was satisfactory, leaving the amount of banknotes on the market not too large. Is it still necessary to firmly withdraw money from circulation and control the amount of money put into circulation?" These remarks are another indication that these comrades, not understanding the basic situation regarding circulation of money on the market, are unable to make a correct appraisal of the relationship between control and stimulation. The withdrawal of money from circulation was satisfactory in the first quarter and, along with the penetrating implementation of economic readjustment, the circulation of money on the market will gradually become normal. But the situation regarding an overabundance of money on the market has not fundamentally changed either nationwide or regionally. The situation regarding circulation of money on the market is an overall reflection of the state of the national economy. The imbalance in the national economy is a problem that has accumulated over the years; therefore, the task of readjustment can by no means be accomplished in 1 or 2 years. Coordinated development of various proportionate relations in the national economy, fundamental improvement in the financial situation, a fundamental solution of the problem of stabilizing market prices, all-round improvement in market supply--all these problems will have to be solved through sustained efforts throughout the period of economic readjustment. And circulation of money on the market, which comprehensively reflects these situations, can only be gradually normalized along with the solution to these problems. To be sure, the circulation of money is not merely a negative reflection of these situations; the vigorous withdrawal of money from circulation and control over money put into circulation will accelerate the effect and progress of the national economy. Therefore, we must maintain firm control from beginning to end and must not slacken this in the slightest. When we talk about the relationship between control and stimulation, we have in mind stimulation tempered by control. If we undertake control but not firmly, or if we simply loosen our grip, this will have a most undesirable effect on economic readjustment, production development, and the stability of people's livelihood.

Money circulates throughout the country and follows commodities. There are many factors in the outflow and inflow of money between various regions. Economic growth may be faster, commodity supply may be better, and circulation of money may also be better in a certain region. However, this is only in the relative or comparative sense. On the whole, the general effect of an overabundance of banknotes on the market cannot but be felt. For this reason, the withdrawal of money from circulation is an important task that must be undertaken firmly and effectively by all regions without exception.

We still remember what some of our comrades said before the beginning of the year: "The withdrawal of money from circulation is a task of overall importance which cannot be undertaken by the banks alone." The situation regarding withdrawal of money from circulation in the first quarter has dispelled the misgivings on the part of some comrades. We hope that the few comrades who still have such misgivings will also stop worrying. At present, party committees and government at all levels have taken the withdrawal of money from circulation as an important task in implementing the readjustment policy and have strengthened their leadership, and all departments concerned working in coordination have taken many effective measures. Now things will depend on how the departments in charge of money circulation move. We should conscientiously carry out the State Council's "decision to tighten credit control and exercise strict control over money put into circulation." We should continue to tighten control where strict control is called for and resolutely stimulate what should be stimulated. Simultaneously with controlling money put into circulation, we must exert great efforts to organize the withdrawal of money from circulation. We should bring the initiative and enthusiasm of the economic departments into play, carry out thorough investigation and research, and give scope to the role of overall reflection. We should carry out a regular study of socioeconomic conditions and of the conditions of the economic departments, correctly analyze problems that arise in light of the overall interests of the national economy, put forward practical measures and methods from the standpoint of economic results, and do a good job under the leadership of party and government organs and in cooperation with the departments concerned.

The tasks for the second quarter and the second half of the year are very heavy and beset with many difficulties. But there are many favorable conditions. As long as we persistently carry out arduous and penetrating work, we will certainly be able to make great contributions to the task of exercising control over the money put into circulation annually.

SPECIALIZED HYDROENERGY PLANNING COMMITTEE SET UP

Beijing SHUILI FADIAN [WATER POWER] in Chinese No 3, 12 Mar 81 p 11

[Text] The Chinese Hydropower Generation Engineering Society held a founding conference for the specialized committee on hydroenergy planning and dynamic economy and an academic discussion meeting in Nanning from 5 to 11 December. Over 100 persons from 52 units of departments, higher educational schools and scientific and research organizations related to the hydroelectric power frontline of each region throughout the nation attended the conference.

During the conference, 35 members were nominated for the first membership on the specialized committee. It was unanimously decided that the main duties of the hydroenergy planning and dynamic economy staff committee should be to develop special topic discussions, exchange of experience and popularization of science, training of personnel and similar academic activities according to the demands of the task of constructing hydroelectric power and plans to develop hydroenergy in our nation, and explore the technical policies related to the major development of hydroelectric power and the feasibility and rationality of major projects. At the present time, special attention should be given to promoting and developing out nation's hydroenergy technology and economy and to developing the function and characteristics of the organization of the society, paying attention to mutual combination and exchange between neighboring scientific fields, and it should serve as a bridge between different departments and fields and provide counseling for policymaking organizations. In 1981, the main activity of the staff committee is to conduct small academic exchanges and organize one or two special topic research classes in coordination with the revision of rules regulating technical and economic computation related to hydroenergy and topics of dynamic economic research in hydroelectric power stations. During the conference an information network for technical and economic information on hydroenergy was set up.

During the academic discussion meeting, comrades of the Guangxi Electric Power bureau systematically described the general situation of planning for the Hongshui River and existing problems. The conference proposed that the nation's related departments and commissions pay attention to the work of development of the Hongshui River, coordinate the plans of related departments, combine them, and give extensive support to the related design units to present feasibility studies, actively organize discussions and reviews, and on this basis, carry out one or more preliminary designs for the first-phase construction so that when the conditions are ripe and the forces are in hand, it can be built in time. As to the basic experience and lessons in hydroenergy planning and technical and economic calculations of hydroenergy, the conference proposed that the nation establish laws and carry out work according to the laws. The state's departments in charge of technical and economic work must strengthen the leadership of each department engaged in technical and economic work, unify research concerned with basic theory and principles, coordinate the technical and economic indicators and parameters, and mutually exchange related information and methods. Related departments must pay attention to training specialized personnel in hydroenergy technology and economy and strengthen scientific research in hydroenergy technology and economy in order to facilitate the progress of the work.

ECONOMY OF HYDROELECTRIC, THERMAL POWER STATIONS COMPARED

Beijing SHUILI FADIAN [WATER POWER] in Chinese, No 3, 12 Mar 81 pp 7-11

[Article by Shixican [2457 3356 3503], Cai Ansi [5591 1344 0934], and Lin Xiangyue [2651 5046 1471] of the Hydrology and Hydroelectric Power Station Teaching and Research Group of the Water Conservancy Department of Qinghua University: "The Problems of Making Dynamic and Economic Comparisons of Hydroelectric and Thermal Power Stations"]

[Text] During the 30 years since the founding of the nation, our nation's hydroelectric power construction has realized definite progress. But among the types of energy consumed throughout the nation, the main resources are still coal and petroleum; hydroelectric power constitutes a relatively small proportion. Therefore, regardless of whether we view the present composition of energy consumption or the proportion of the amount of hydroelectric or thermal power generation, we see that the scale of our nation's hydroelectric power construction and our nation's rich water energy resources are not well matched.

Why has hydroelectric power not developed faster? One important reason is that for a long time, the study of the economy of hydroelectric power construction in producing electric power was not given the proper emphasis. Scientific research and statistical analysis concerning the study of the economy of hydroelectric power did not develop well, and even related standards lacked the necessary rules concerning the study of the economy of hydroelectric power. This situation should not continue and it must be changed quickly.

I. Use of the Number of Years for Compensation and for Return on Investment

In the economic comparison of development plans for electric power construction projects, each plan must have the following comparable conditions: Each plan must satisfy the demands of development of the national economy; must be technically feasible; must be assured the required manpower, material and capital; and must be compared on the same basis regarding consumption costs, price index and time factors. Otherwise, incorrect conclusions may be drawn from the comparison.

To prove the economic results of the plans, they must take into account the quantity of the product to be provided (amount of power generated, amount of water supply), the quality (percentage of assurance, voltage, cycles, water quality), productivity (installed capacity, amount of flow of water drawn), raw material and fuel consumption, actual indicators of flooding and moving, and the economic indicators expressed in monetary units of investment, cost, profit, and the number of years for a return on investment of the project. Therefore, there should be a whole set of technical and economic indicators for use to measure the economic results of the plans on an overall basis. In this system of indicators, the number of years for a return on the entire investment and the number of years for compensation of the investment balance are two relatively important comprehensive indicators. Each of these indicators has its use and they should not be confused.

To account for the economic results of labor required and labor consumption on an overall basis, when making an economic comparison of different plans in the combined electric power system of both hydroelectric and thermal power stations (for example, when making an economic comparison of plans for the installed capacity and plans for different reservoir parameters), the method of the number of years for compensation of investment differences of the system was used. In recent years, some people have also used the number of years for a return on total investment of the hydroelectric power station or the number of years of retrieval of the differences in investment for hydroelectric power stations as the criteria for economic comparison of the plans. The formula for calculating the number of years for a return of total investment is:

$$T_{\text{return}} = \frac{\text{investment}}{\text{net income}} = \frac{\text{amount of investment}}{\text{gross gain - annual cost}}$$

The number of years for a return on total investment in an engineering project is an important indicator to measure the economic results of investment in an engineering project, but it cannot serve as a criteria for economic comparison of plans. This is because as the scale of the hydroelectric power station grows, the rate of increase in investment will speed up, and after reaching a certain scale, the rate of increase of gain will become slower and slower; if in an economic comparison the plan with the shortest number of years for a return on total investment is chosen as the best plan, then the scale of the hydroelectric power station may be too small.

Using the number of years of retrieval of investment differences between two plans for a hydroelectric power station, $T_{\text{return}} = \frac{\text{Investment Differential}}{\text{Net Income Differential}}$ as the criteria for comparing the plans is similar in form to the method of using the number of years of compensation, but they are different in principle in two points: 1) The method of the number of years of compensation (or calculated expenditure method) is used to measure the merits of a plan based on the economic results of the entire system of electric power generation consisting of hydroelectric and thermal power stations. The method of the number of years of retrieval of investment differences of hydroelectric power stations does not consider the effects brought about by the economic gain to thermal power stations in the system as a result of a change in the plans of the hydroelectric power station. Therefore, the best plan viewed simply on the basis of the economic results of the hydroelectric power station itself may not be the best plan for the entire electric power system consisting of hydroelectric and thermal power stations. 2) The method of the number of years of compensation has a prerequisite requiring that the annual demands of industry and agriculture for electric power load and generated capacity are satisfied jointly by hydroelectric and thermal power stations in the system. It is a kind of criteria for the most suitable plan for the selection of hydroelectric and thermal power stations and for dynamic and economic comparison of hydroelectric and thermal power stations of the electric power system. The method of the number of years of retrieval of the investment differences between two plans for hydroelectric power stations does not take into consideration how to satisfy the needs of the load and the generation capacity of the system, and it does not make a dynamic and economic comparison with the thermal power stations in the system, so it cannot be used as the criteria for the selection of the most suitable plan for hydroelectric and thermal power stations in the system.

Therefore, the indicator of the number of years for the return on total investment of a hydroelectric power station and the indicator of the number of years of retrieval of investment differences between two plans for a hydroelectric power station are both unsuitable for comparing the dynamic and economic properties of plans for the generation of electric power by hydroelectric and thermal power stations and for use as the criteria for economic comparison to determine the rational scale of hydroelectric and thermal power stations. But the number of years for return on total investment in a power station serves an important function in mutual comparison and cross-reference among power stations, and it is an important indicator to measure the economic results of investment.

II. Accounting for the Investment Indicators

Investment in capital construction is a comprehensive indicator of the manpower, materials and financial capital required to realize the capital construction project expressed in monetary units. It can generally reflect the material labor used by the engineering project. After deducting the retrieval cost from the investment in capital construction of a power station and floating capital investment, we arrive at the building cost, which constitutes the fixed capital of the power stations. According to preliminary statistics, the total building cost of our nation's hydroelectric power stations averages about 87 percent of the total investment. Therefore, accounting for the capital used by the power station should be based on the building cost. In this article, the traditional term construction investment is still used, but it refers to the cost of building construction.

When making an economic comparison of the plans for hydroelectric and thermal power generation, calculation of the investment in the hydroelectric and thermal power station (plant) should be made on the same basis to assure the comparability of the plans. But in the past, the investments in hydroelectric power stations and in thermal power plants were not calculated on the same basis, and thus the investment in hydroelectric power stations ordinarily appeared to be much greater than the investment in a thermal power plant of the same capacity, giving rise to the mistaken concept that the average investment per kilowatt of installed capacity of a hydroelectric power station was far greater than that of a thermal power plant; in the economic comparison of the hydroelectric power station and the thermal power plant, the hydroelectric power station is at a disadvantage, and to a definite degree, this has affected the development of hydroelectric power construction. Here there are mainly three problems: 1) In the construction of large, medium and small hydroelectric power stations, most possess comprehensive gains in flood prevention, irrigation, water supply or shipping. But when calculating the investment in construction, the necessary investment distribution among the various sectors of comprehensive utilization of water conservancy resources was not made or was seldom made, and thus the investment in hydroelectric power stations appeared larger. 2) When calculating the investment in thermal power stations, the necessary investment for the construction of coal mines and railroad construction was not included, and thus the numerical value of the calculated investment for thermal power plants was smaller. 3) Because the number of years of construction necessary for the development of coal mines directly related to the thermal power plant were not included, it was generally believed that the number of years required for the construction of a hydroelectric power station was much longer than for a thermal power plant.

For these reasons, in electric power construction, the view that "the investment in a hydroelectric power station is much larger than a thermal power station and that the period of construction is much longer than that of the thermal power station" has been popular for a long time. This does not coincide with the actual situation.

In the following, several problems in the calculation of investment will be separately discussed:

1. Problem of Distribution of Investment in Construction of a Hydroelectric Power Station

A hydroelectric power station project built for comprehensive utilization not only provides the gain of power generation, but it also provides comprehensive gain in many aspects such as flood prevention, irrigation, water supply, shipping, and fish culture. In examining the economic results of investment of such a project, especially when compared with the economic results of thermal power, it is obvious that the gains in every aspect should be considered, not considering only the gain of hydroelectric power generation and ignoring the economic gains in other aspects. When separately evaluating the economic results of each water department of the project, the economic gain obtained by each department from this project must be calculated separately, and at the same time, the investment in this project should be rationally dispersed among all sectors.

In the economic calculation of projects of comprehensive gain, we must disperse the investment in the project so as to analyze in greater detail the investment gain of the entire project and account for the economic result of investment of each department using water especially, so that the investment borne by the hydroelectric power station is more rational; thus, in making economic comparisons of the development plans of hydroelectric and thermal power generation, a more correct evaluation can be made. If we believe that since under socialist conditions, investments in construction projects are all funded by the state anyway and that it is not necessary to expend efforts to study the problem of dispersion of investment and if we include all investment in the cost of hydroelectric power stations, creating a false view of large investment in hydroelectric power and giving rise to an incorrect conclusion unfavorable to the development of hydroelectric power, then this will produce an unfavorable effect upon the development of the entire national economy. In addition, if we do not consider dispersion of investment, if we do not carry out the necessary analysis of the economic results of investment for each department using water, then sometimes inappropriate and overly high design standards and demands upon departments using water will be proposed, and this will also inappropriately enlarge the scale and investment in the project. Therefore, implementing a rational dispersion of investment is entirely necessary. This is needed not only in doing things according to economic patterns, it is also beneficial to coordinating the conflicts among the departments using water and to stimulating each department to propose rational design standards and demands in planning and design.

Many methods have been proposed to disperse investment in key hydroelectric power construction projects; for example: 1) proportional dispersion according to the economic gain obtained by each department using water; 2) proportional dispersion according to the investment required by substituting measures of each department possessing the same gain; 3) proportional dispersion of investment required by each construction project when developing single projects of each department; 4) proportional distribution of the capacity of the reservoir used by each department; 5) proportional dispersion of the amount of water utilized by each department, 6) proportional dispersion of the investment in specialized buildings of each department of the construction project. There are also other methods, which will not be listed here.

Among the various methods of dispersion of investment described above, the first method, in principle, is relatively more rational: it is to allow the investment borne by each department to possess the same investment gain coefficient; but the difficulty is that the calculation of the gain of some departments is more complex, and the calculation of the gain of each department in flood prevention, electric power generation, irrigation, water supply, and shipping lacks a unified and comparable foundation both in principle and method. But to correctly evaluate the economic gain of investment in a construction project, including the unavoidable calculation of the economic gain of each department, the calculations should be gradually perfected and coordinated on the presently available basis of the methods for calculating the gain of each department. All of the other methods have shortcomings, but under specific conditions they can also be tried.

2. The Problem of Including Corresponding Investment of Coal Mines and Railroads in the Investment of Thermal Power Plants

The energy for our nation's thermal power plants is mainly coal; the amount of coal used for generation of electric power constitutes about one-sixth of the total amount of coal produced, so power generation is one of the major users of coal. In the past, when making economic comparisons of hydroelectric and thermal power stations (plants), only direct investment in the thermal power plants themselves was calculated, while the consumption of coal used for fuel each year was included in the annual operating costs of the thermal power plants according to the price of coal shipped to the plants. Because of the difference between price and value, the price of coal was slightly lower, and this shifted a portion of the net income which should have been obtained from the production of coal mines to the thermal power plants, and thus exaggerated the economic gain of the thermal power plants.

Because coal is a necessary gross commodity needed for consumption to maintain the production of the thermal power plants, especially when coal and railroad shipping in our nation are both in tight supply, building a new large-scale thermal power plant correspondingly requires building new or expanding some coal pits and coal mines and increasing the investment in railroad transportation. Therefore, the construction or expansion of coal mines and railroads should be regarded as a component part of a newly built thermal power plant system; the investment in coal mines and railroads built to supply energy to the thermal power plants should be included in the investment of the thermal power plants. If we calculate on the basis of an annual consumption of 3.5 million tons of raw coal to produce 1 million kilowatts by the thermal power plant, and the investment in capital construction of the coal mine per ton of coal is 100 yuan, then building a new coal mine producing an annual yield of 3.5 million tons requires about 350 million yuan of investment in capital construction. For each kilowatt of installed capacity of the thermal power plant, an increase of 350 yuan of investment in coal mines is needed, and adding the corresponding investment in railroads, the investment per kilowatt of the thermal power plant system approaches 1,000 yuan. If we consider dispersion of the investment in public construction projects of the hydroelectric power network and thus reduce the investment borne by the hydroelectric power station, then the investment per kilowatt of hydroelectric power and of thermal power is not too different.

3. The Time Factor in Investment Accumulation

Whether for a hydroelectric power station or a thermal power plant, in calculating the investment, we should include in the construction period the accumulated loss in investment produced by failure of the investment to develop, so as to assure comparability of each plan according to the time factor. Under ordinary situations, the cumulative loss in investment in hydroelectric stations is larger because the construction period is longer, but in the calculations of a thermal power plant system, we should also include the corresponding cumulative loss in investment of the coal mine, and the construction period of the coal mine is also relatively long.

The effects of investment during the period of construction and the time factor should include the following three parts: 1) The loss in the accumulation of capital for construction and cooperation which could not be given to society to provide gain; the loss of this portion can be calculated by the investment gain coefficient demanded and the capital used. 2) The loss produced by visible and invisible loss of buildings and facilities already built before they begin production; this part of the economic loss can be estimated by depreciation of the buildings and facilities already built. 3) The increased cost of construction due to an extension of the construction time; for example, wages of construction personnel, administrative costs, and maintenance costs of various enterprises;

this part of the loss should be estimated based on actual situations and calculated in the investment plans for each year during the construction period.

Consideration of the time factor of investment accumulation coincides with the objective economic pattern and assures the comparability of each plan in economic comparison; it is beneficial to promoting and hastening the progress of construction, shortening the time of construction, and it can spur part of the construction to enter into production earlier during the construction period so that the investment can produce a gain even faster and increase the economic result of investment.

III. Accounting for Annual Production Costs

Annual production costs are the total of the various costs expended each year by the enterprises in the production of products. It approximately reflects labor consumption in production and is the accounting reference of unit cost of products of enterprises. It is also an important indicator for a comparison of the plans of hydroelectric and thermal power stations (plants).

In the cost of electric power sales of each electric power network in our nation, fuel costs constitute 56 percent and depreciation costs constitute about 20 percent. In the cost of electric power generation by the thermal power plant, fuel costs constitute 60 to 70 percent and even more. In the cost of electric power generation by a hydroelectric power station, depreciation constitutes about 60 percent and more. Therefore, these two costs affect the economic comparison of the plans of hydroelectric and thermal electric power stations (plants) to a great extent, and it is necessary to give them full attention.

1. The Problem of Depreciation of Fixed Assets

Depreciation of fixed assets includes basic depreciation and depreciation due to major repairs. These two costs constitute 16 percent and 4 percent, respectively, of the cost of electric power sales.

Basic depreciation is the value of fixed assets expressed in monetary units transferred to the products due to visible or invisible losses. The basic depreciation of fixed assets currently in force in our nation generally does not take into consideration the invisible losses, and basically, the withdrawal and deposit each year are calculated by the number of years of the fixed assets used.

From 1971 to 1977, the average basic depreciation of our nation's electric power industry was about 3 percent, and the basic depreciation of certain hydroelectric power stations was only 2 percent. If we consider invisible loss, the number of years of depreciation of fixed assets should be shorter than the useful life, i.e., the basic depreciation rate should appropriately increase.

2. Problem of Fuel Costs in Thermal Power Plants

In the cost of electric power generation by thermal power plants in our nation, the proportion of fuel costs is about 72 percent in high-voltage heat supply type power plants and high-voltage steam condensation type power plants, and about 62 percent in sub-high-voltage steam condensation type power plants. The fuel costs as a proportion of the cost of electric power generation are not only related to the type of power plant, but are also related to the scale of the electric power plant. For example, the fuel consumption cost in a thermal power plant with a single generator capacity of 200,000 to 300,000 kilowatts is about 56 percent, while that in a thermal power plant with a single generator capacity of 100,000 kilowatts is about 76 percent, and in a thermal power plant with a single generator capacity of 25,000 to 50,000 kilowatts it is about 80 percent. It can thus be seen that in the economic comparison of plans for hydroelectric and thermal power stations, full attention must be paid to comparing and selecting the type and scale of the plants to replace the thermal power plant.

Hydroelectric power stations with a definite regulatory reservoir capacity frequency serve to regulate peaks and frequency in the electric power system. To assure comparability of the plans, the plans in which a thermal electric power plant is substituted should also correspondingly consider the consumption of standard coal required in regulating the peaks and frequencies. For example, in 1976 there were two electric power systems, in which the number of hours of utilization of installed thermal power generation was 3,300 hours and 6,080 hours, respectively, while in the consumption of standard coal for electricity generation, the former was 1.48 times that of the latter. In addition, if we include the corresponding investment in coal mines and railroads in the investment of thermal power generation, then in calculating the annual operating costs of thermal power generation, we cannot calculate the cost of coal consumption by the thermal power plant according to the price of coal shipped to the plant, but we must calculate the production cost and the transportation cost of coal.

IV. Problem of the Investment Gain Coefficient

The investment gain coefficient is an important economic indicator in the economic comparison of plans for hydroelectric and thermal power stations. In 1956, the Ministry of Electric Power Industry issued dynamic design standards for hydroelectric power stations and it suggested the use of a compensation of 10 to 15 years, i.e., the established investment gain coefficient was 0.1 to 0.067. Later, some units used a compensation of 5 to 7 years in planning and design, i.e., an investment gain coefficient of 0.15. As to the investment gain coefficient which electric power departments should use, this still has not been standardized, and it should be established as soon as possible. We believe the following factors should be considered:

1. When establishing the investment gain coefficient of each department and enterprise, we should refer to the average investment gain coefficients actually realized by the various material production departments of the national economy and the trends in their development and evolution. For example, in the 1960's, the average number of years of investment retrieval of the entire society of our nation was about 6 years, i.e., the entire society's average investment gain coefficient was about 0.16. The concerned economic leadership departments can establish the average investment gain coefficient of the entire society and of industrial departments in accordance with the demands of development and using

the actual conditions of economic development of our nation as important reference factors for establishing the investment gain coefficients of the departments of each sector.

2. In the development of our national economy, as electric power is the first to be developed, the demands upon the investment gain coefficient of the electric power department can be slightly lower than for other material production departments to facilitate development of the electric power industry as a priority.

3. Considering the rational utilization and the long-range benefits of energy, hydroelectric power should be developed extensively in the construction of electric power; therefore, when making economic comparisons of hydroelectric and thermal power, we can use slightly lower investment gain coefficients to stimulate the development of hydropower for electric power generation so that hydroenergy resources can be more fully utilized, thus conserving coal and petroleum resources.

4. The established investment gain coefficient should have a definite scale of variation so that suitable indicators can be selected in accordance with the characteristics of various aspects of the energy, natural and economic conditions of different regions of our nation.

V. Conclusion

1. Our nation's hydroenergy resources are very rich, but at present only 2.5 percent have been developed. Some of the reasons were that economic studies for electric power construction were not given the proper emphasis, economic accounting and the method of analysis did not completely coincide with the actual objective situation and the economic patterns, and for a long time the incorrect view prevailed that "even though hydropower generation is good, it requires a much larger investment than thermal power generation," thus affecting the development of hydroelectric construction.

2. To simultaneously calculate the economic results of labor consumption and labor used, in the past when doing economic comparisons of proposals for electric power construction we have generally used the method of the term of repayment and the least expenditure method of calculation of investment differences of the systems. Although these have had shortcomings, they are relatively rational, and the annual expenditure method of calculation is more convenient to use than the method of the term of repayment. Although the number of years of return on total investment or the number of years of retrieval of investment differences are important technical economic indicators, they are unsuitable as standards for judging the merits of the plans in economic comparison of hydroelectric and thermal power plants.

3. When carrying out dynamic economic comparison of the plans for hydroelectric and thermal power stations (plants), the investment in hydroelectric power and thermal power generation and the scope of calculating the production costs should all begin from the supply of energy and extend to the time when electric power is transported to the region of electric power users. For the hydroelectric power station, accounting for the investment and the operating costs which should be borne should take into consideration related reservoir engineering projects,

hydroelectric power plants and transmission and transformer power construction as a unified hydroelectric station system. For thermal power generation, accounting for the investment and the operating costs which should be borne should take into consideration related coal mines, railroads, thermal power plants, transmission and transformer power engineering construction as one thermal power station system.

4. The magnitude of investment gain coefficients to be used by the electric power departments still lacks sufficient study, and efforts should be organized to conscientiously carry out research.

5. In the work of electric power construction, economic study should be strengthened greatly, and scientific research in related fields should be actively developed. In the present situation, the various problems existing in past theoretical and analytic work should be summarized, and at the same time, the various economic theories and methods that benefit our nation's socialist construction should be conscientiously absorbed, so that hopefully we can finally establish a set of standards and calculation methods for economic comparison that suit the actual situation of construction of our nation's electric power industry.

MERITS OF PUMPED STORAGE POWER STATIONS DISCUSSED

Beijing SHUILI FADIAN [WATER POWER] in Chinese No 3, 12 Mar 81 pp 40-42

[Article by Wang Yifu [3769 0122 1788] of the Huadong Survey and Design Institute of the Ministry of Electric Power Industry: "Clarification of Several Problems Related to Our Nation's Construction of Pumped Storage Power Stations"]

[Text] In some regions in our nation, especially in northern China, eastern China and the northeastern regions, where the number of large peak regulating hydroelectric power stations which can be newly built is small, we should begin research in the construction of pumped storage power stations. But some comrades have raised some questions concerning our nation's construction of pumped storage power stations. They can be condensed into five questions. Some opinions are presented to clarify these questions.

I. Our Nation's Hydroenergy Resources Are Rich and the Degree of Exploitation and Utilization Is Low; Isn't It Too Early Now To Talk About Building Pumped Storage Power Stations?

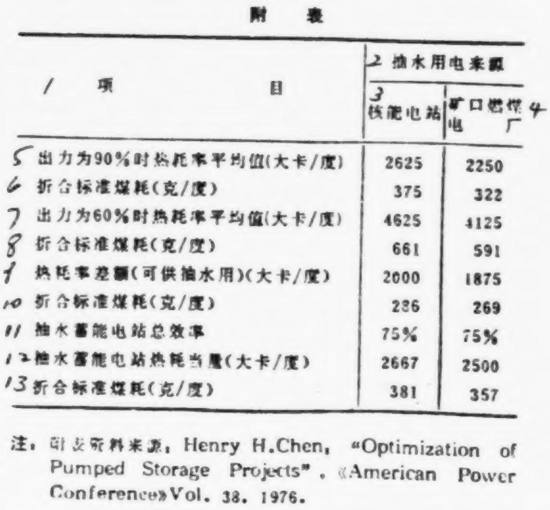
The reserve of hydroenergy resources is indeed very rich. Calculating the amount of hydroenergy resources that can possibly be exploited and utilized for power generation, they are equivalent to the annual generation of 1.9 trillion kilowatt-hours, but the amount developed so far is less than 3 percent, and the rate of utilization is also indeed very low. They are also unevenly distributed among the regions of our nation. They are mostly concentrated in the southwest, south-central and northwest regions, constituting 94.4 percent, whereas the northern, northeastern and the eastern regions have only 5.6 percent. Coal resources in northern China are of high quality, the reserve is large, and they lead the nation, but hydroelectric energy resources are lacking; the latter are mainly concentrated in the middle reaches of the Yellow River. The development of that section of the river involves the problems of comprehensive utilization for flood prevention, irrigation, power generation and blocking sand, and it is far from the major users of electricity in the regions of Beijing, Tianjin and Tangshan. Therefore, the peak regulating capacity of the electric power network in northern China must depend on large pumped storage power stations and large thermal power stations used specifically to regulate peaks. The northeastern and eastern regions are our nation's important industrial and agricultural bases, and they lead the nation in the amount of electricity generated by the two electric power networks. But the two regions are not self-sufficient in coal, which has to be imported from other regions. The hydroelectric power stations already built or being built utilize 25.7 percent of the hydroenergy resources that may be developed in the northeast and 20.6 percent in eastern China. Of the hydroenergy resources that have not been exploited yet, some power stations have been asked by other departments using water to limit their operations, and thus hydroelectric power cannot be completely used for regulating peaks. Some electric power stations are far from the load center, and require ultrahigh voltage transmission and transformer equipment. Some reservoirs have displaced many people, the area of cultivated land being submerged is large, construction investment has been increased, and some projects can hardly be built. In the northeast, some power stations are situated on rivers that form international borders, and they cannot be easily developed right now. Therefore, in the near future, the number of large hydroelectric power stations that can be built and can share the work of regulating the peaks of the main networks in these two regions is few. Also, an economic study of similar types of peak regulating power stations (including pumped storage power station) is needed as part of the long-range planning for the electrical power system in order to select the best. Therefore, at present, we should firmly undertake to do well the preliminary work for river hydroelectric power stations and pumped storage power stations, clearly understand their conditions of construction and economic results, and based on need and possibility, build them selectively; it is not too early to carry out this urgent task in today's hydroelectric power construction.

II. The Pumped Storage Power Station Is a Type of Electric Energy Conversion and Storage Measure Which Consumes Energy. When Our Nation's Supply Is Tight and Capital Is Limited, Do We Have the Strength To Build Pumped Storage Power Stations?

The present pumped storage power station total efficiency is between 70 and 75 percent. It is commonly said that pumped storage power stations use 3 to 4 kilowatt-hours in exchange for providing 2 to 3 kilowatt-hours of electricity. At first glance this seems to be an irrational consumption of electrical energy, but actually it is not so simple. Let us first examine the seasonal regulation by the pure storage power station. During the flooding period, it utilizes the surplus force of the electric power system to pump water, converting electric energy into potential energy from water stored in the reservoirs of mountain valleys. When the dry period arrives, the water is used to generate electricity to supply the electric power system. If the surplus force during the flooding period is not utilized, it will be wasted, and the electric energy produced during the dry period is like an assured force of the hydroelectric power station, it has the same value of utilization. Obviously, this converted economic value cannot be measured only superficially in numerical values.

The daily (weekly) regulatory pumped storage power station's working principle is also the same. It utilizes the surplus capacity to pump water and store energy during the low trough load period of the thermal power plant or nuclear power station, and generates electricity when the load is at high peak. Because the thermal efficiency of the basic load thermal power plant (or nuclear station) is different from the peak load thermal power plant (the unit consumption of coal of the basic load is lower than the peak load), according to foreign data, "even when the efficiency of one cycle of a pure storage power station is 70 to 75 percent (calculating the electrical energy), the fuel energy consumed by the high-efficiency pump may approach or be smaller than the fuel consumed by the less efficient peak load thermal electric power generator substituting for the storage power station's generators in generating electricity." Utilizing the surplus forces of the basic load to pump water for generation of electricity at the time of peak load also means consuming the fuel of which we have rich reserves (coal) and conserving fuel that is in short supply (oil and gas).

Furthermore, the rate of heat loss of a thermal power station or a nuclear power station, when other conditions (such as characteristics of the generators, load characteristics, operating conditions, fuel quality, etc) are the same, decreases as the capacity of the power station (the ratio between the average output of the power station within a definite period and established capacity) increases. A U.S. report shows the heat loss under different average output of some nuclear power stations and coal-fired power stations at mines. The figures have been selected, converted and listed in the following table.



附　表

1 项　　目	2 抽水用电来源	
	3 核能电站	矿口燃煤电厂 4
5 出力为90%时热耗率平均值(大卡/度)	2625	2250
6 折合标准煤耗(克/度)	375	322

1. Item
2. Source of electricity for pumping
3. Nuclear power station
4. Coal-fired power plants at mines
5. Average value of heat loss at 90 percent output (kilocalorie/kilowatt-hour)
6. Converted to loss of standard coal (gram/kilowatt-hour)
7. Average value of heat loss at 60 percent output (kilocalorie/kilowatt-hour)
8. Converted to loss of standard coal (gram/kilowatt-hour)
9. Difference in heat loss (can be used for pumping water) (kilocalorie/kilowatt-hour)
10. Converted to loss of standard coal (gram/kilowatt-hour)
11. Total efficiency of pumped storage power station
12. Equivalent value of heat loss of pumped storage power station (kilocalorie/kilowatt-hour)
13. Converted to loss of standard coal (gram/kilowatt-hour)

Source of data: Henry H. Chen: "Optimization of Pumped Storage Projects," "American Power Conference," Vol 38, 1976.

We can see from the accompanying table that when the thermal power plant or the nuclear power station in the electric power system is operating at a reduced output, the fuel consumed for each kilowatt-hour of electricity increases a lot; therefore, the generators should operate evenly and close to full load to conserve fuel costs. But there is always a difference between the high peak and the low trough on the load graph. At low trough, several thermal power plants or nuclear power stations must also operate at reduced output; at some thermal power plants the generators even have to be shut off and wait to be turned on again just before the high peak, thus increasing unit consumption of coal and creating invisible waste. If the system has a pumped storage power station, then when the load is at a low trough it can use electricity to pump water, and thus the operating condition of the thermal (nuclear) power plants can be improved, their capacity can be increased, and their unit coal consumption can be lowered. Therefore, even though storage power stations use electricity to pump water, partial compensation can be obtained from the avoidance of invisible waste by related power stations.

III. Our Nation's Electricity Pricing System Is Different From That of Industrially Developed Nations; We Do Not Differentiate Between Peak and Base Loads. Is There Any Economic Gain in Developing the Pumped Storage Power Station in Our Nation?

The price of electricity in foreign nations varies in different seasons and the time of use of electricity. For example, in the joint system in Western Europe, generally speaking, the price of electricity at peak load during the daytime in winter is about three times the price at night. The price of electricity during the peak in the daytime in summer is about two times that at night. Because of the difference in the structure of the power source of the electricity network of each nation participating in the joint operation and the different cost of generating electricity, the prices of exchange of electric power between the networks are also not entirely uniform. For example, Switzerland is at the center of the joint system, and it owns a massive amount of seasonally adjusted electric energy; therefore at night it takes in the cheapest low trough electrical energy from foreign nations for domestic consumption, including electricity used by the storage power stations, while during the daytime at high peak, the seasonally adjusted hydroelectric power station and storage power station generate electricity to supply their own nation and foreign nations. The quantity, time and price of exchange electric power between the systems are determined by normal commercial negotiation between the power companies. In the costs of generation of electricity of the storage power station, the cost for pumping water is about 40 to 50 percent; adding fixed costs of depreciation, operation and maintenance, the cost is still much cheaper than other peak load power sources, so it is competitive. For the other power systems, at the low trough they can increase output of electric power and thus reduce cost, while at high peak load they can buy electric power at a lower cost than producing it themselves and thus realize a gain, and this is profoundly welcomed.

In the unified power system, as the load increases, whether to increase the building of pumped storage power stations or other types of peak regulating power stations must be considered on the basis of the technical and economic results of the entire system for comparison and selection. Besides considering river hydroelectric stations as a priority, in foreign nations, there are also fast start-up generators used specifically for regulating peak loads and generators of the condensed steam type which can operate at variable voltages. Sometimes regular large-scale thermal power generators have to be used to share the burden of the mid-load or the peak load. Economic comparison of the peak regulating thermal power plant with the pumped storage power station shows that the main differences are: the peak regulating thermal power plant's building cost per kilowatt-hour (not including costs of coal mines, shipping equipment) is lower, while the annual costs are higher. The annual costs include fixed costs (depreciation, operation, maintenance, major repairs) and fuel costs that increase or decrease according to the amount of electricity generated. The building cost per kilowatt-hour of the pure pumped storage power station is slightly higher than that of the ordinary thermal power plant, but the annual costs are lower. The annual costs also include fixed costs and the pumping costs that vary with the amount of electricity generated.

According to statistics of foreign nations, the construction cost per kilowatt-hour of the pure storage power station is about 100 to 130 percent of the peak regulating thermal power plant; the civil engineering construction part constitutes a larger proportion, the useful life of the electromechanical facilities is also longer, and therefore its basic depreciation and fixed costs are all lower than those of peak regulating thermal power plants. The pumping costs of storage power stations are generally believed to include only calculations of the direct increases in fuel costs to generate electricity used for the supply of pumping water for the power station (because other expenditures do not increase or decrease with the use of electricity for pumping water). This fuel cost approaches or is smaller than the fuel cost of the peak regulating thermal power plant. In addition, the economic gain obtained from the use of electricity supplied by the related power station for pumping water, the gain from the adjustment of frequency by the storage power station, the gain from supplying zero work output, the gain from serving as a backup in case of accidents or loss in receiving and transmitting electric power if the storage power station is relatively far away from the power source for pumping water and the load center, must all be calculated item by item. The entire economic analysis frequently shows that the pumped storage power station provides the cheapest and most reliable electric power to satisfy the need for regulating peaks, and realizes many gains for the system.

IV. The Development of Pumped Storage Power Stations Abroad Began With the Mixed Type and Then Developed Into the Pure Storage Type. Should Our Nation Also Develop the Mixed Type First and Then the Pure Storage Power Station?

Checking the course of development of pumped storage projects of each nation, we see that there is no set pattern as to the type of power station. At the end of the last century, Switzerland built the world's first seasonal regulatory pure storage power station. Later, the comprehensive utilization hydroelectric power stations of many nations could not completely operate according to the needs of the electric power system because of the demands of irrigation, shipping and water supply departments, and so pumped storage facilities became mixed power stations to respond to the need for regulating peaks. Some hydroelectric power stations added pumped storage generators to utilize surplus output during low loads in the system and to increase the capability to regulate peaks. The United States has built the most pumped storage power stations. Before the 1950's, two hydroelectric power stations already built were utilized to install reversible generators that could pump water and generate electricity in order to obtain experience in design, manufacturing and operation. After the experiments were successful, pure storage power stations developed rapidly on a large scale. The three pumped storage power stations built in the early days in Japan are equipped with normal hydraulic turbine generators and electric water pumps. During the past 20 years, because the number of hydroelectric power stations on rivers worth developing has lessened, in accordance with the needs and possibilities of rebuilding and expanding the existing hydroelectric power stations, we should build new storage power stations in a big way.

The pumping and generating facilities of mixed power stations can fully utilize the hydraulic buildings and facilities of power stations. If the costs of damming rivers and reservoirs are not included, the unit building cost is cheaper than that of pure storage power stations of the same capacity and using the same flood peak. During the flooding period, some additional seasonal electric power can be obtained. This is a favorable condition of the mixed storage power station. But it also has an unfavorable side. First, it is limited by the conditions of natural resources and social and economic conditions. Its geographical position and the scale of its construction are unlike those of the pure storage power station, which are almost unrestrained by the limitations of the river and water flow and which can be selected more widely. In our nation's eastern and northern regions, the number of mixed storage power stations which can be built for the major networks is few; their flood peak is mostly under 100 meters. A low flood peak has a large amount of flow, and the corresponding storage generators, regulatory reservoirs and water pipes and channels must all be larger; therefore, the cost is higher than the pure storage power stations with a high flood peak. Second, the falling depth of reservoirs of hydroelectric power stations over rivers is generally 40 to 50 percent of the highest flood peak. Such a large variation if not readjusted frequently renders the single-speed reversible generator unsuitable, and two-speed generators have to be used, thus increasing the building cost of the generator and the cost of maintenance. The best sites for hydroelectric power stations on rivers frequently are far away from the load center and the pumping power source. Sometimes they are too remote and the loss in power transmission is too large, and so it is not suitable for them to add storage generators.

Pure storage power stations do not rely on the natural falling differences and the discharge, there are more choices of sites for the stations, the reservoir capacity is smaller, and the loss of area covered by water is smaller. The design standards for hydraulic buildings are lower and large spillways are not needed. During construction, expensive flow guideways are not needed, construction is not affected by flood water, and construction can be carried out throughout the year. Therefore, the construction cost per kilowatt-hour of pure storage power stations, according to statistics of building such power stations by foreign nations, is only 40 to 50 percent that of power stations on rivers, and the unit cost for power generation including the cost of pumping is only slightly higher for storage power stations. The statistics of domestic plans present a similar picture. In recent years, the unit construction cost of power stations on rivers has differed more markedly from that of the pure storage power stations because of the relatively large increase in the cost of moving reservoirs.

The building cost of the pure pumped storage power station when the capacity and the storage capacity are the same generally drops as the flood peak heightens. The higher the effective flood peak, the smaller the flow and the reservoir capacity required, and therefore the unit building cost is lower. Therefore, foreign pure storage power stations are developing toward a high flood peak: the highest flood peak of mixed flow type pump and hydraulic generators already reaches over 500 meters. But we cannot say accordingly that "the water source of the storage power station must be above 500 meters," because the height of the water source is only one factor that determines the building cost of the power station; it is not the only factor. For example, our nation is still at the beginning period of building storage power stations, we lack experience in the design and manufacturing of reversible water pump and hydraulic generators; we must start out from this actual situation, and for the pure storage power stations to be built in the near future, it appears that a flood peak of 150 to 250 meters and a single generator capacity of 100,000 kilowatts are more suitable.

In general, when our nation's electric power networks build storage power stations in the future, regardless of the locality, type, scale, etc, everything must be based on the objective conditions of the locality, and the best time and the best type must be selected after seeking truth from facts through technical and economic comparisons. We must follow the principle of doing things according to natural patterns and economic patterns.

V. Have We Found a Superior Site for a Storage Power Station in the Eastern China Region? Can the Electric Power System Assure Power for Pumping?

Since 1973, the Eastern China Electric Power Administration Bureau has organized concerned units to survey southern Jiangsu, southeastern Anhui, northern Zhejiang in the area of the load centers and the ultrahigh voltage lines in the regions north and south of the Huai River, and Xuzhou up to northern Zhejiang and southern Jiangsu, and has found nine possible sites for power stations. At present, the Eastern China Survey and Design Institute of the Ministry of Electric Power Industry is doing further work to examine the building conditions at each site in order to select the best plant site.

The daily load graph of the electric power system shows natural peaks and troughs. In industrially developed nations, the late night low trough loads frequently reach only 50 to 60 percent of the peak load, and so there is a definite surplus capacity which can be supplied to storage power stations for pumping. During the 10 years of chaos in our nation, electric power construction lagged behind the need for power, there was a shortage in the supply of fuel for thermal power plants, hydroelectric power stations were out of control, and the supply of electricity by each electric power network was in short supply. Taking the Eastern China electric power network as an example: around 1975, it was deficient in power and in capacity, and measures to use electric power by shifts had to be carried out. At high peaks, frequently limitations had to be imposed on the use of power. But beginning in 1979, when the policy of readjustment of the national economy was implemented and carried out, each factory implemented cost accounting and became responsible for its own profit and loss, the conflicts in the supply and the use of electric power within the network gradually improved, the daily load factor gradually dropped to 87 percent, and the lowest load factor dropped to 73 percent. The quality of the cycles and voltage all met the standards. In the future, the proportion of consumption of electric power by the light and textile industries and by the people for daily living in the Eastern China region will further improve, the proportion of electric power consumption by the industries that consume large amounts of power will drop relatively, and therefore the daily load factor will continue to drop; it is estimated that after 10 years, if the highest load within the network reaches 16 million kilowatts, the peak and trough difference will be over 5 million kilowatts. For the safety, versatility and economic operation of the network, the optimum combination of various types of peak regulating power stations should be used. Besides the hydroelectric and thermal power stations (plants) that are operating, being built or being planned, it is necessary to consider plans for pumped storage power stations. An installed capacity of several hundred thousand to a million kilowatts will serve to cut the peaks and fill the troughs. Such a large difference between the peaks and the troughs in the entire network should provide sufficient surplus capacity for electric power for pumping. Sites for storage power stations at Fushan in Fanchang and Fahaiwu in Suzhou have superior building conditions and technical and economic indicators and they are worth further study. In view of the above situation, we suggest that a pumped storage power station of over 200,000 kilowatts be built first in the eastern region. Instead of workers working at night, it can use the electricity at night to pump water so as to generate electricity the next day during daytime. Its entire building cost, including compensation for extra wages for overtime, can be retrieved within 2 years after operation begins. By using it, several hundred thousand workers who use electricity on shifts will be able to return to daytime labor, wealth will be created for the power network, and experience will be gained in the building of large pumped storage power stations in our nation.

HYDROLOGICAL SURVEY WORK ESSENTIAL IN HYDROPOWER CONSTRUCTION

Beijing SHUILI FADIAN [WATER POWER] in Chinese No 3, 12 Mar 81 pp 3-6

[Article by the Planning Department of the Hydroelectric Power Construction Bureau: "Several Opinions Concerning Hydrological Survey Work in Strengthening Hydroelectric Power Construction"]

[Text] I. Major Achievements

Hydrological survey work is an important part of the early stage of hydroelectric power construction. Since the founding of the nation, hydrological survey work has realized great achievements and has contributed its share in the construction of hydroelectric power. This is mainly manifested in the following:

1. A technical team has been trained in hydrological surveying, and a group of specialized hydrological survey stations directly serving hydroelectric power construction has been established. At the beginning of the 1950's, hydrological survey work for hydroelectric power was basically a blank. According to statistics of the hydrological departments, at the time of liberation, basically the nation had only 353 hydrological survey stations, and information was extremely deficient. There were no hydrological stations along the rivers where hydroelectric power stations were being planned, such as the Yili River, Liulangdong, or the Lushui River in Yunnan. The work to determine the hydrological and meteorological characteristics of the power station localities and to provide the necessary hydrological data for the design of the power stations was very difficult. We conducted training classes and trained a group of young people, and through work and practice, they quickly became a technical and hydrological survey team which could carry out hydrological tests, hydrological surveys and organize hydrological data. By 1958, the number of hydrological survey personnel directly serving hydroelectric construction grew to 1,400 persons; 400 specialized hydrological survey stations of various types were established (after 1958, some of the hydrological survey stations were placed under local jurisdictions); and various types of observational, surveying and investigative work were launched, filling the deficiency in observational data and basic stations of the nation, and the necessary hydrological and meteorological information was gathered for our nation's hydroelectric power construction.

2. Testing facilities were renovated, testing methods were improved, testing accuracy was improved, and a reliable reference was provided for the rational

determination of engineering and hydrological calculations. During the 1950's, equipment used to test the flow of water was relatively simple: generally the surveying boat was anchored and a tachometer was used to measure the rate of medium and low speed flow. Measurement of high speed water flow was mainly dependent upon a buoy. The precision of the information was low. In the 1960's, most of the survey stations used cables of floating cranes pulled across the river to measure the speed of flow; individual stations also set up electrically powered cables and improved the capability of measuring the flow by the tachometer. During recent years, hydrological cables have become the major flow measuring equipment of our nation's hydrological survey stations; the scale of flow measurement using the tachometer has grown greatly, and favorable conditions have been created for improving the quality of testing. Of the presently existing 14 specialized hydrological survey stations of the hydroelectric power system, 9 have set up electrically powered flow measuring cables. In July 1976, the Naigesha special hydrological station built for the Lubuge Power Station Design Institute at the Huangni River in Yunnan, using the cable tachometer, measured the greatest peak flow of flood water since the founding of the station in 1958, and the water level-flow relationship curve was rationally revised accordingly. The designed peak flood flow for each 10,000 years was revised from 12,700 cubic meters/second to 9,350 cubic meters/second; therefore the scale of the original design of the flood relief structure of the power station was changed, allowing the saving of capital for the state.

3. In combination with the design needs of hydroelectric power stations, greater achievements have been realized in specialized surveying and experimental research. For example:

A. The observations and surveys of ice conditions, investigations of ice conditions, and forecasting and research on the formation of rivers carried out for the reservoir region of the Second Baishan Power Station of Songhuajiang and its upper reaches served well to solve the problems of draining ice and guiding the flow during the construction period of the Baishan Power Station. The data obtained from the observation and research of the ice conditions of the Yellow River and its upper and lower reaches for the reservoirs of the power stations at Liujiaxia, Yanguoxia and Qingtongxia also provided precious measured data and practical experience in analyzing the conditions of the formation of ice jams and ice dams and in the method of calculating ice jams.

B. In the analysis and calculation of floods in the design of the Ankang Power Station on the Han River, observation and study of the specific drop of flood water on the section over 10 kilometers downstream from the power station revealed that the downstream valley acts to control and confine the water of the measured flow section during high water level periods; the specific drop of the water surface slows down as the amount of flow increases. From this pattern, the originally established water level-flow relationship curve was revised, and based on this, we calculated that the peak flow of each historical flood was less by 7.3 to 13.3 percent. This rationally readjusted the design of the peak flow of floods so that the standards for construction to handle floods were improved without changing the designed peak flow of floods.

C. Experimental research on reservoirs carried out on the Yanguoxia, Qingtondxia and Liujiaxia reservoirs along the Yellow River showed in time the changes in alluviation of incoming water and incoming sand in front of the dam and in the reservoir and provided a scientific basis for proposals on the rational utilization of the reservoir. For example, observation of the abnormal density currents of the tributary Tao River flowing into the Liujiaxia Reservoir (the average amount of sand over many years flowing into the Liujiaxia Reservoir constitutes 30.6 percent of the total amount of sand entering the reservoir) enabled us to grasp the opportunity and the appropriate time to open a drain in order to extract the sand and to improve control of the rise of the alluvial surface in front of the dam and the amount of sand passing through the generator. Experience in the operation of the Qingtongxia Reservoir and the results of extracting sand were summarized by analyzing the data on tests of the mud and sand.

D. During the latter part of the 1950's, testing and research on shoved and shifting mud and sand were carried out in the Xinan River and the Min River. At present, testing and research of large shoved and shifting pebbles are continuing at the Jiangshe Dam and in the Baisha River on the upper reaches of the Min River. Preliminary achievements have been realized in the method of testing and in the efficiency of experiments to develop sampling machinery and sand extraction.

E. Observations of water surface evaporation were carried out at the special hydrological stations on the Xinan River, the Fengman Reservoir, Shangquan on the Yellow River, the Shangyou in Jiangxi, the Mapei in Shangzhi in Hunan, and Fuxian Lake in Yunnan. However, because most of the test stations were reassigned to local authorities, the gathering of data stopped. In 1975, using Yangzuoyong Lake in Xizang for the study of hydroelectric power generation in natural lakes, because of a lack of sufficient information on water surface evaporation on plateaus, an evaporation observation field was established in the empty land next to the lake; an evaporation pool of 20 square meters was built and different types of evaporation bowls were used for comparison and observation. The Xiaodeshi special hydrological station on the Yalong River established for the Ertan Power Station also set up large evaporation pools to carry out observation and research in evaporation.

In addition, when building hydroelectric power stations in karst regions where hydrogeological conditions are complex, leakage of the reservoir is also a key problem. In analyzing the pattern of leakage of a reservoir and judging the development of leakage, hydrological surveying and research are also important means. For example, it was discovered that the Shuicaozi Reservoir in Yunnan leaked after it began storing water, and through analysis of hydrological and observed data, we found the scope of the leakage and were able to understand the pattern of leakage and to provide a scientific basis for correctly establishing procedures to handle the situation.

II. The Main Tasks at Present

In 30 years, our nation's hydrological work has undergone great change. The basic network of hydrological stations of the nation has developed greatly (as of the end of 1978, the nation had 17,584 hydrological test stations of various types), testing equipment has been improved, the precision of the various types of observed and test data has been improved to varying degrees, basic hydrological information can be provided for hydroelectric power construction, and compared to the 1950's the situation has visibly improved. In the new situation at present, to adapt to the needs of the development of hydroelectric power construction, we believe the following three aspects should be grasped well.

1. Distribution of special hydrological testing stations. At present, the development of the nation's basic network of hydrological stations is not evenly spread throughout the nation. The density of the network of stations in the southwest and the northwest is still sparse, and the water energy resources in these regions are extremely rich, especially in the southwest, where the reserve of water energy resources constitutes over 70 percent of the nation's reserve of water energy resources. The presently existing basic hydrological stations cannot satisfy the demands for hydroelectric power plans and designs in these regions. For example, the mainstream of the Lanchang River valley, which is about to be developed, extends for 2,000 kilometers in our nation, but at present there are only five basic hydrological stations there. Therefore, while actively seeking the cooperation of hydrological departments to hasten and increase the establishment of basic stations, the present planning and design needs must be taken into account in planning for the development of hydroelectric power construction, and a group of special hydrological stations must be established on the present foundation of the network of basic hydrological stations. In other regions, where certain hydrological aspects of the rivers are more complex, the presently existing network of basic stations cannot control the characteristics of water and sand, and so when the present network cannot meet the demands of hydroelectric power construction design, special hydrological stations must also be added.

2. Observation of the water level at plants and dams. Except for the damsites where hydrological stations have already been built, generally water level observation stations need to be established at plant sites and damsites to gather information on the water level and the flow on the upper and lower reaches of the dam in order to draw a water level-flow relationship curve for the plants and dams. The number of water gauges to be established depends mainly on the situation of the rivers in the dam area and the concrete demands of engineering design.

3. Specialized hydrological surveys and experimental research. Because a lot of the information needed in the design of power stations cannot be observed and measured by ordinary basic hydrological stations, specialized survey and research work must be organized. For example: 1) To fully grasp the characteristics of the testing station, observation and testing of the patterns of variation in the specific drop of the surface of flood waters within a relatively long section downstream from the section of the testing station must be carried out. 2) Comparative tests of the buoy coefficients and the flow velocity coefficients of the water surface must be conducted. 3) Ice conditions in the river channels and reservoirs of frozen rivers must be observed and studied. 4) To study flood water entering reservoirs, hydrological observation and testing of the evolution of flood waters in the reservoir area and the unstable flow in river channels must be carried out. 5) Observation and experimental research in hydrology and mud and sand of reservoirs must be carried out. 6) Observation and study of

evaporation of water surfaces must be conducted. 7) Hydrological observation and research in special regions such as hydrological surveys of karst regions and observation of leakage of reservoirs must be conducted.

Under ordinary conditions, when carrying out the planning of river valleys (river sections), after fully studying the various aspects of technology and economics and after selecting the river section for the first-phase construction, we must immediately consider carrying out and strengthening testing work which serves as a reference for various methods of engineering and hydrological calculations for the test stations (basic station or special station) and we must establish the observation of water levels at plants and dams. When there are too few basic hydrological stations, when the hydrological situation is complex, or when the presently existing stations cannot control the characteristics of the water and sand of the rivers, proposals should be submitted to the hydrological departments to establish more basic stations as soon as possible, and when necessary, consideration should be given to the establishment of special hydrological stations. During the preliminary design stage, besides continuing to carry out the various observations and tests during the planning stage, the necessary ground surface meteorological observations must also be carried out to supplement the information needed regarding the climatic characteristics of the dam area. Consideration must be given to the planning of a network of water (rain) forecasting stations to carry out flood forecasting during the construction period. According to the actual situation, when necessary, consideration must also be given to drawing up plans for experimental research work for the reservoir after the reservoir has been built. Also, special surveys and observation and research work related to the items described above must be carried out. The content of the work and the estimated funds required to carry out these observations and tests as well as the personnel needed must be correspondingly included in the documents to be submitted together to the higher authorities for review.

Because hydrological survey work is more important during the beginning period of hydroelectric power construction than other aspects of work, the tasks must be considered, planned and carried out early.

III. Several Suggestions

The present situation of hydrological survey work for the hydroelectric power system and the demands of the development of hydroelectric power construction are very much out of step. Leadership must be strengthened urgently and measures must be taken to change the situation.

The technical force presently available is only one-fourth that available in 1958, the average age of the technical personnel is older in general, and the scientific and cultural level is lower. According to incomplete information and statistics of the several design institutes, the average age of the workers in hydrological surveying is over 45 years, and many are unsuited for continued field survey work. The technical cadres of the hydrological survey teams constitute about 30 percent, and among them, those with a cultural level of university and college education constitute only about 10 percent. The number of various types of special hydrological test stations is nine-tenths less than the number existing in 1958 (some were placed under the jurisdiction of the local hydrological departments), the testing equipment is outdated and backward, and the equipment has not been renovated for many years. Therefore, to enable hydrological surveying work to adapt to the trends of modernized construction, and fully satisfy the demands upon hydrological work in the various stages of design, construction and coperation, we suggest the following:

1. We must emphasize hydrological survey work. Many years of practice prove that where the hydrological survey work has begun early and the work has been done fully, the results of hydrological analysis used as the basis for planning and design of construction along the river have been more rational. Conversely, where the work has been passive, it has even affected construction. Each level of leadership should give sufficient emphasis to hydrological survey work, strengthen the leadership, and insist on correcting the mistaken view that hydrological survey work is not important or even that hydrological analysis can be carried out without hydrological survey work. Without carrying out a definite amount of geological survey work, it is not possible to propose a reliable geological conclusion; without complete hydrological survey data, similarly it is not possible to provide reliable hydrological data. At present, the significance of hydrological survey work in hydroelectric power construction has not been fully recognized, so the work cannot be done, the difficulties of the work cannot be easily solved. This situation should be quickly turned around, each level of leadership must grasp hydrological survey work as tightly as it has grasped geological survey work to establish a firm and reliable foundation for hydroelectric power construction.

2. We must build up the teams. During the beginning period of the 1950's, because we built up the survey teams, work progressed rapidly. Now, our forces have been weakened, the organization and the agencies are not sound, some design institutes even today do not have agencies and personnel in charge of hydrological survey work, and the work cannot be carried out. In the face of this situation, each design institute must rapidly establish hydrological survey teams and further reorganize and make sound the already existing special agencies. New agencies should be quickly strengthened. Institutes that have not yet established specialized agencies must rapidly assign personnel to establish an organization and quickly begin work. During the course of establishing work teams, we must first undertake the technical training of cadres and workers, such as conducting operations training classes and training and learning sessions during the dry period. Where conditions permit, personnel can be sent to related schools for training, and through various means we must improve the scientific, cultural, technical and operational levels of the workers. Second, we must strengthen the work of political ideology, revive the spirit of hard struggle existing during the 1950's, revive the good traditions and workstyle resolutely, and in particular, we must strengthen the education of young workers so that they can learn conscientiously and work without worries. We must care about the workers, especially workers who work long periods in the field stations; we must care about their learning and their lives and concretely solve their actual difficulties, fully mobilize the enthusiasm of the broad masses of workers, and build up hydrological survey teams that are well trained, versatile, and suited to the characteristics of hydrological surveying work for hydroelectric power construction.

3. We must strengthen management of the test stations. To assure the quality of the research results and the test data, we must establish a sound system of regulations. During the period of interference by the extreme leftist line, many effective regulations were abolished, creating chaos in production. In the present new situation, efforts must be made to study the needs of the work and to supplement and establish new working systems and technical regulations; for example, the duties of the technical positions of each level, how to implement the "four simultaneous tasks" in testing work (simultaneous testing, calculating, organizing, analyzing) to assure precision of the test data, organization and review of data, technical safety and operation of the test stations, and use and maintenance of instruments and equipment should all be subjected to practical regulations and included in working systems, and during the course of implementation we should continuously summarize the experience and gradually perfect the operation. At the appropriate time, we must study the actual situation of hydroelectric and hydrological survey work and establish and supplement technical regulations on the foundation of the "hydrological testing trial standards" of the hydrological departments.

4. We must improve the methods, means and quality of testing. In recent years, there has been a definite improvement in the equipment and method of testing. But many problems still exist. For example, continuous research and improvement are required in measurement of the flow at high water levels, extraction of sand by cable, and testing of shoved and shifting materials. In particular, we should study the use of electrical measurements, automatic recording, long-distance communications and computers and similar new techniques in testing methods and organization of data, keeping in view the characteristics of the work of hydrological testing stations specifically for electric power generation so as to assure the quality of the data and the safety of the testing work, and testing equipment should be developed that is light weight and convenient, easy to transport and easy to assemble. On the basis of our actual situation, we should learn the advanced experience in hydrological survey work at home and abroad, appropriately introduce new types of instruments and equipment from abroad, and improve the standard of testing techniques.

5. In accordance with the task of planning and design for hydroelectric power, we should establish plans for hydrological survey work for the next 2 to 3 years. Combining the planning and design tasks of one's own unit, we should study and draw up working plans for the next 2 to 3 years to serve as the basis for launching the work. The plans should include the distribution and reorganization of specialized hydrological testing stations, specialized hydrological surveys and experimental research, reform of the testing equipment, and how to implement organizational measures and technical measures. As to the distribution of specialized hydrological stations, we should first consider establishing them along rivers in border regions where the water energy is rich and where the network of the state's basic stations is sparse. This is a strategic work. In the early days of the founding of the nation we paid attention and took more initiative in the work; now we must strengthen that work. The establishment of specialized hydrological testing stations must be different from the state's basic hydrological stations: the distribution must be decided on at an early stage, the construction must be quick, and after the plans have been completed, they can be transferred. To assure that the plans are carried

out smoothly, in drawing up the plans we must closely match the requirements of the plans and the design, and we must fully carry out surveys and research to insure that they are practical.

6. The responsible departments must start out by doing a good job of building the early stage foundation work for hydroelectric power; the necessary material foundations must be provided to solve well the problems of funding, equipment and personnel for hydrological surveying and experimental research, which must be carried out early to assure the smooth progress of the work.

ENERGY

SERIOUS LONG RANGE BIOGAS PRODUCTION EFFORTS REPORTED

Wuhan HUBEI RIBAO in Chinese 12 Jul 81 p 1

[Article: "Hubei Province's Biogas Construction Begins To Take Root Among the Masses; Seeking After Truth in Facts and Proceeding From Reality in Everything"]

[Text] The program of seeking truth in facts and proceeding from reality in doing everything, advocated by the CCP Central Committee, has sparked biogas construction in Hubei Province.

Statistics from relevant departments show that in the 3 year period since 1978, 134,000 new biogas pits have been constructed in Hubei, 2½ times the number built in the 12 year period from 1958 to 1977. Half the newly built biogas pits were built last year when there was an agricultural disaster and funds were comparatively scarce. This situation demonstrates that during the past several years, biogas construction in Hubei Province has developed fairly rapidly, that biogas construction has begun to take root among the masses, and that its reputation is going higher and higher.

Hubei Province's rural villages have a severe shortage of firewood. As early as 1958, in a search for new rural energy sources, some places began to pool funds to make biogas. Subsequently, because of a tendency toward overanxiousness to get results and oversimplified and rapid planning in the guiding mentality, many places proposed unrealistically high standards, onesidedly emphasized conservation or substitution, did not seek quality, and did not put emphasis on benefits. As a result, after several flipflops, and various ups and downs, by 1977, more than 30,000 of the 52,000 biogas pits constructed had become ailing or abandoned pits. The masses attributed these ailing and abandoned pits as gripe pits saying, "A waste of work and use of money for nothing; it would have been better to have lost it doing something else."

Since the 3rd Plenary Session of the 11th Party Central Committee, a policy of proceeding from realities has been followed in biogas construction. First of all, on the basis of economic conditions in individual places, the extent of firewood shortage, the labor foundation and technical strength available for making biogas, biogas construction has been divided into four different kinds of counties. Some are required to spread biogas throughout the county; some are to extend their use of it; some are to have more demonstration areas; and some are to operate only test sites. In this way, the biogas construction battlefront is shortened, leadership relatively strengthened, and limited material resources and funds put to better use. Second is the abandonment of the former lopsided seeking after quantity and replacing it with emphasis on quality in the building of pits, and measures being adopted, at the same time, to assure quality in construction. Methods include spread of a system of contracts for pit construction, formulation of training tests, and acquisition of certificates of proficiency by biogas technicians before undertaking construction. Some counties have also set up special biogas service companies.

There is a concern for benefits and steady development so that biogas can establish a new reputation among the masses, and develop faster rather than slower. In 1980, the province used about the same amount of funds and cement as in 1979 for biogas construction, but 75 percent more pits were constructed than in 1979, and the pit success rate was better than 97 percent. Luoji Commune in Zhongxiang County is a place with a serious firewood shortage where, as a result of steady development, 58 percent of all peasant households in the commune have built biogas pits. In the course of a year, the commune has conserved 8.97 million jin of vegetation used for firewood; commune members have increased manure collections by 280,000 man-days; and production teams have saved 84,000 yuan that would otherwise have been spent for fertilizer. Shuangyan Production Brigade, Yaqueling Commune in Yichang County, which could not assure proper quality construction watched others for 2 years and waited for 3. After taking action to assure pit construction quality, the masses realized benefits, and this production team has developed biogas everywhere in only a year.

ZHEJIANG OFFICIAL OUTLINES REQUIREMENTS FOR INDUSTRIAL GROWTH

Hangzhou ZHEJIANG RIBAO in Chinese 26 Jun 81 p 1

[Article: "Expansion of Sources of Raw Materials and Conservation of Energy To Maintain Hubei Province's Steady Industrial Growth Pointed Out by Li Fengping [2621 6265 1627] in Analysis of Industrial Production Situation at Provincial Industrial Exchange Conference"]

[Text] How can Zhejiang's industry grow steadily and continuously? On 24 June, the final day of the provincial Industrial Exchange Work Conference, Li Fengping, the provincial governor, spoke in detail about Zhejiang Province's industrial production situation, giving emphasis to analysis of the underpinings and weak links in Zhejiang Province's industry. He emphatically pointed out that the key to maintenance of steady and continuous growth of industry lies in a fundamental policy in which self-reliance is dominant and getting outside support is ancillary.

Comrade Li Fengping said that since the smashing of the "gang of four," and particularly since the Third Plenary Session, Zhejiang's industrial production has developed very rapidly. Last year total industrial output value for the province was two and one-half times that of the period before the smashing of the "gang of four." Between January and May of this year, output value had increased 13.5 percent over the same period last year. These accomplishments were the result of the CCP Central Committee's correct leadership since the Third Plenary Session, and the result of the implementation by people throughout the province, particularly by the broad masses of cadres and workers on the front line of industry and transportation, of the "Eight Character Policy." However, the difficulties Zhejiang industry faces in continuing steady growth are considerable. Energy is in seriously short supply; there are many shortages in raw materials; capital is scarce and problems in foreign trade exports are numerous. Therefore, our leadership comrades on all echelons must maintain clear heads and not develop feelings of arrogance and conceit as a result of the rapid growth of industry during the past several years, nor should they develop apathetic and pessimistic feelings because of the fairly numerous hardships to be faced. If leadership comrades on all levels will diligently carry out a fundamental policy in which self-reliance is dominant and gaining outside assistance is ancillary, will rely on the broad masses, and actively do a good job, these hardships can be surmounted, and the industry of Zhejiang can continue steady and protracted growth.

More than 70 percent of the raw materials for Zhejiang's light textile industry derive from agriculture. A dependable road to self-reliant solution of the problems of raw materials for the light textile industry is planned building in rural villages of various kinds of raw materials bases. Raw materials bases may be built for cotton, hemp, silkworm cocoons, sugarcane, sheep wool, rabbit fur, lumbur, mao bamboo, aquatic products, leather, various minerals, fruits, vegetables, etc. In short, the farming industry and the hatching industry of rural villages can be built into bases for industrial raw materials. Some of these industrial raw materials may be given to industrial units for processing, and some can be rough processed by communes and brigades, the semifinished products given to industrial units for fine processing. The building of raw materials bases should be combined with the development of diversification in rural villages, and should be led by planning departments, with the participation of industrial, agricultural, forestry, commercial, supply and marketing, and foreign trade departments in making a raw materials production plan. Next industry, foreign trade, and supply and marketing departments should form direct links with rural communes and brigades to establish raw materials bases. The building of raw materials bases will not necessarily require the use of grainfields. Zhejiang Province has spacious mountain areas, sea beaches, hills, and river flats, which should be fully developed and used, adapting general methods to local situations for the building of various kinds of raw materials bases. In the building of raw materials bases, there has to be an adherence to the principle of equality and mutual benefit. Industrial plants and rural communes and production brigades must be linked together and sign economic contracts, which are examined and authenticated by industrial and commercial administration and management departments, each bearing economic and legal responsibilities. In order to do a good job in the building of raw materials bases, the three echelons of province, prefecture, and county should establish raw materials base funds, allotting money from reserve financial resources to make non-interest bearing loans. Subject to concurrence of fiscal departments, industrial departments and industrial enterprises should allocate some funds for construction of raw materials bases.

The shortage of energy is not a short-term matter, but a long-term one the solution to which lies in conservation. Right now, energy is short, while at the same time energy waste is a common phenomenon. This is very serious in some places and departments. Therefore, it is necessary to implement the pertinent instruction of the CCP Central Committee and of the State Council to devote serious attention to conservation work. There are three ways of doing this. One is inciting the masses so that every individual saves. The second is adoption of economic measures and administrative measures. The third is improvements in wide-ranging economic cooperation. Any ideas which a person thinks he can carry out himself without seeking the help of others are unworkable. In Zhejiang Province, in particular, where processing industries are numerous, and the proportion of market adjustments great, economic cooperation is all the more necessary. In our economic cooperation, we must keep our eye on cooperation to have a flow into the province of raw materials that are in short supply here, in order to enliven production. It is necessary, first of all, to do a good job among prefectures within the province and among departments. Everything must be done in accordance with the principle of equality and mutual interest, mutual exchange between haves and have nots, and use of strengths to make up for weaknesses. Some can supply raw materials; some can provide semimanufactured goods and odd components; others can supply technology and equipment. The forms of cooperation may be diversified, as for example joint industrial and trade, joint agricultural and commercial, joint agricultural and trade, etc. So long as it can promote production and can arouse the enthusiasm of all quarters, any form may be adopted. The focus of cooperation with other provinces lies in organizing the importation of fuel and raw materials, and bringing in of technology and equipment that Zhejiang Province lacks to launch domestic compensatory trade and to receive goods brought in for processing. For this purpose provincial and prefectural cooperation offices should be strengthened and broughtup to necessary strength. In addition, it is necessary to launch economic exchange activities outside the country, and actively get into processing of materials brought in from foreign traders, bring in specimens for use in writing orders, bring in parts for assembly, and engage in compensatory trade and joint capital ventures. The prevailing management system is overly centralized, has numerous links, and a proliferation of procedures. This should be gradually changed. Different projects should be permitted a relaxation of jurisdiction for examination and approval, and a simplification of procedures to enliven the economy.

At the conference, Comrade Li Fengping also said that for Zhejiang's industry to continue stable and protracted development, it was also necessary to intensify administration and management work. He said we should study advanced domestic and foreign administration and management experiences, and train large numbers of administrators and managers in order to elevate the administration and management of Zhejiang's industry, commerce, and foreign trade. There should be a planned dispatch of sales personnel and technicians to rural villages, to other provinces, and even to foreign countries to understand market changes and the needs of consumers, to promote sale of products, and to purchase raw materials. Every means should be used to spread information over a wide area about name brand goods, traditional goods, and high quality goods, using newspapers, broadcasts, television, advertising, trademarks, samples, and explanation booklets. Information should be disseminated not only inside China, but also in the Hong Kong-Macao market and in foreign countries. Once sales work has been enlivened, Zhejiang's industrial output will enjoy wide markets.

Finally, Comrade Li Fengping spoke on the issue of combining scientific research and production. He said that without this provision, continued, stable, and protracted development of Zhejiang's industry would not be possible. The development of both the domestic and foreign economies has more and more demonstrated the importance of science and technology. In maintaining quality and quantity of existing industrial manufactured goods, in developing and increasing output of new goods, and in making technological improvements in enterprises alike, if one departs from science and technology that is like a "blind man riding a blind horse"; it simply will not work. Conditions in Zhejiang are very good in this regard. There is Zhejiang University, Hangzhou University, agricultural universities, medical schools, and the Zhejiang Academy of Engineering. There is also a group of researfch organizations in the Provincial Academy of Agricultural Sciences, and numerous scientists and technicians in industrial and mining enterprises. Zhejiang Province has made achievements in scientific research in the past, and progress has been made in the spread of research results. However, some industrial departments and industrial enterprises give insufficient attention to research, and they do not pursue vigorously the application of research results. Some industrial departments even refuse to use research results. Such attitudes are extremely wrong. Leadership comrades at all echelons must increase their understanding, make full use of the role of scientists and technicians of all kinds, and actively spread the results of research to promote development of production.

Comrade Di Xiwu [5049 5047 2976], the deputy governor, also spoke at the conference.

The Provincial Industrial and Transportation Work Conference began on 6 June and lasted a total of 9 days. Delegates to the conference included leadership comrades responsible for industry in all prefectures, municipalities, and counties, responsible personnel in economic committees and financial offices, and comrades in charge of relevant departments at the provincial level and in provincially operated plants and mines, totaling more than 300 people.

ECONOMIC REFORM IN SICHUAN PROVIDES VALUABLE EXPERIENCE

Hong Kong CHING-CHI TAO-PAO (ECONOMIC REPORTER) in Chinese No 23, Jun 81 pp 4-7

[Article by Lin Ling [2651 0407]: "Reform of China's Economic Organization Tested in Sichuan"]

[Text] An experiment in reform of the economic organization was begun in China's Sichuan Province in the fourth quarter of 1978. The reform was conducted in accordance with the guiding principles determined by the Third Plenary Session of the 11th Chinese Communist Party Central Committee. The objective of the experiment was to test, without creating a great disturbance, whether the present economic system, with its principal characteristic being highly centralized administration and management, could be transformed to suit the characteristics of China's socialist economy--an economy that would fully develop the regulatory function of the market under the guidance of state planning--to suit the needs of developing productive force and accelerate the advance of the four modernizations.

The biggest drawbacks to our country's economic management system are, for one thing, that authority is too centralized, and for another, in eating from the common pot, enterprises become an accessory to the administrative organ, depending on the superiors to come and move the "abacus beads," and fettering the initiative and activism of the enterprise and the workers. This creates economic rigidity and loss of mobility. Our country has carried out many reforms of the economic system since the founding of the nation, but these involved mainly the delimiting of boundaries between central and local authorities, and documents as to whether the central or the local authority was to control the enterprises. These [reforms] concentrated only on motivating the activism of the center and the locals, and paid no attention to mobilizing that which directly bears a burden of building the socialist economy--the activism of the enterprises and the workers--and so the result was that no matter how much they were reformed, the [reforms] never touched any vital parts of the system and were extremely unsuccessful.

After the smashing of the "gang of four," a movement to liberate thinking was begun in our country, encouraging us to reexamine socialist economic theory in the light of almost 30 years of our practice. Through conscientious discussion, we gradually realized that our socialist economy, besides being a planned economy, is also a commodity economy. Enterprises under the system of ownership by all the people are opposite independent commodity producers. Our country's economy cannot be brought to life until the management system is reformed in accordance with the principles of commodity economics, the principles of socialized large producers, and the principles of socialism, motivating the activism and initiative of the enterprises and the workers. Starting from this realization, Sichuan chose the path of trial reform of the system by taking as a point of departure the expansion of the authority of enterprises to decide for themselves.

The experiment in expanding the authority of enterprises to make their own decisions was conducted initially in six industrial enterprises; in 1979 it was extended to 100 industrial enterprises and 40 commercial enterprises. As of the present, 417 industrial enterprises, 250 commercial enterprises, and a few transport and construction enterprises have been selected as the test base. In this way we will be able to promote reform of the management system in planning, materials, commerce, finance, banking, capital construction, and other fields to a relatively large degree.

The point of departure for expanding the authority of enterprises to make their own decisions is: liberate the enterprise from the fetters of the existing system and make it truly become a socialist commercial producer. To achieve this, we require a developmental process. This process more or less includes: implementing retention of a portion of the profits, appropriate expansion of the enterprise plan arrangements, marketing of products, and expansion of authority in re-production and such areas; implementation of "independent accounting, figuring taxes as profits, and assuming sole responsibility for profits and losses" (here we should explain that with enterprises under the system of ownership by all the people, because the means of production are owned by all the people, most of the enterprise's profits must be turned over to the state; when the enterprise suffers a loss, the state must still guarantee basic living expenses to the employees; therefore, this sole responsibility for profits and losses has a certain relativity); liberate the enterprise from its subordinate relationship to department and districts; and make the enterprise truly able to carry on production management activities independently under the guidance of the national plan. At present a great many enterprises in Sichuan are practicing retention of a portion of the profits, and five enterprises are trying to practice sole responsibility for profits and losses.

There are a great many problems associated with the beginning of expansion of the authority of enterprises to make their own decisions, and the principal of these are in five areas: Should enterprises be given definite planning authority, or should they be allowed to organize production according to the requirements of the market under the national plan? Should enterprises be given specific product marketing authority, or should they be permitted to sell part of the product, including the means of production, on their own in the market? Should enterprises be given specific economic benefits, or should they be permitted to retain part of the profits, depending upon whether management has been good or bad, to serve as enterprise capital? Should enterprises be given the authority for a specific expansion of re-production, or should they be permitted to raise their own capital for development of potential, renew, rebuild, and expand reproduction according to the value of their fund?

Should enterprises be given specific personnel authority, or should enterprises be permitted to carry out their own recruiting of workers and promoting of cadres? The posing of these problems of course touches on the various aspects of the present system and on the traditional theoretical concepts that are reflected in the present system. This will provide a kind of bottom-to-top motivation for the reform of the economic system, and it will provide an objective basis for carrying out the reforms correctly.

After 2 years of experimentation, it is no longer possible to assume that a socialist enterprise can carry out production only according to targets that are like instructions from the state, because an enterprise can set up its own supplementary plans outside the state plan, according to the needs of the market, and can make its own adjustments where the state plan does not suit the need of the market. This without doubt represents a great reform in the planning system. The fetters are of the theory that the means of production are not commodities have already been broken, and except for a few products that have to do with the national economy and the people's livelihood, dangerous goods like explosives, and products that are in short supply, which are still subject to unified purchase and allocation, most means of production go into circulation, and an enterprise can satisfy its requirements either through direct supply contracts or through free purchases in the market. The system of unified purchase and exclusive selling rights has been replaced by several forms of buying and selling, such as unified purchase, pick and buy, negotiated purchase, self-marketing, etc. Enterprises can market a portion of their product themselves, and large shops can lay in stock directly from the factory, without going through the wholesale stage. The core of the reform is the acknowledgement that enterprises under the system of ownership by all the people occupy a primary position as far as the national welfare is concerned, and that they should have their own relatively independent economic interests. This is something that could not be discussed or thought of in the past. Now an enterprise can enjoy a certain profit proportionate to whether the management has been good or bad and can use it to develop potential, renew, rebuild, and otherwise expand re-production as directly related to simple re-production, or to provide increased bonuses to the employees or improve their collective welfare. The principal investment is still controlled by the state, however, and enterprise investment must be appropriate to the guidance of the state plan, bank funds must be subject to control, and norms have been set for any increase in wage funds. The only thing that has not been reformed to any extent is the labor system. Because our country must keep as many people employed as possible, we are not able to select and recruit only the best.

These reforms have caused what has always been considered a resource alien to the socialist economic system--market regulation--to enter into our economic lives and begin to become a powerful force invigorating our economy.

Traditional theory assumes that under conditions of socialism, the law of value has no regulatory function in the sphere of production. After an enterprise formulates supplemental plans according to the requirements of the marketplace and then carries out production accordingly, supply and demand changes in the market begin to regulate the direction of employment of the enterprise's capital, and to transform the enterprise from one working only to complete its duties to one working for the needs of the market. As far as the enterprise is concerned, this is a fundamental change, greatly transforming the situation in which production was divorced from requirements. It shows that the production sphere cannot be separated from market regulation.

Traditional theory assumes that the law of value has a regulatory effect in the sphere of circulation but limits it to the circulation of consumer goods, excluding from it the means of production and thus creating a serious disjointing of supply and demand. This is the same as winding oneself up in a cocoon. The reform has put large amounts of the means of production similarly under the effects of the market mechanism and has brought about a marked improvement in the situation of supply and demand separation.

In the final analysis, market regulation is a question of price. Although we have not yet carried out a reform of the price system, the implementation of market regulation made it impossible that what is now in effect simply a planned price structure would not come into conflict with it. From the present view, this price structure has already begun to disintegrate, and four forms of prices have begun to appear: (1) Fixed prices--principally those means of production, livelihood materials, and a relatively large portion of commodities--still employ prices set by the state. (2) Floating prices--principally those means of production for which supply exceeds demand, such as electrical machinery products, etc.--float under prices set by the state. (3) Negotiated prices--principally a few commodities for which supply cannot match demand--have prices arrived at through negotiation between buyer and seller. (4) Free prices--which are the trading prices in rural markets, and which change with the changes in market supply and demand. This transformation of the price structure will readily allow some prices to rise, but in general its use has for some time begun to alter the situation of deviation between prices and values, opening the way for the full employment of price leverage to encourage the development of production.

The most striking effect of market regulation is that its influence on the economic benefit to the enterprise gets greater and greater, and the economic benefit to the enterprise has already begun to become linked with the competitive capability of its products in the market. When competitive ability is strong, economic benefits are large; when competitive ability is weak, economic benefits are small. In this way, competition, viewed by traditional concepts as a characteristic of capitalism, can appear quite unwittingly between enterprises engaged in the same trade. Market competition is like a formless but powerful propeller, moving the enterprise to produce, at all costs, products of good quality and low cost and of sorts that suit the market, to provide good service, and to obtain the greatest economic benefit, and constantly urging backward units to emulate those which are advanced. Sichuan is one of China's relatively backward districts as far as industrial development is concerned. The quality and variety of local industrial products are far from being the equal of those in the coastal areas. In the past they adopted a policy of protection, restricting products from the coastal areas from entering the Sichuan market, assuming that this would allow local Sichuan industries to develop. However, the result was just the opposite. Now competition has destroyed this protection policy, and large quantities of products from the coastal areas are pouring into Sichuan. People are concerned that local Sichuan industries will lose out in this competition. The facts tell us that competition on the one hand has presented a serious threat to local Sichuan industry, but at the same time it has provided a strong impetus that no administrative force could match: it has encouraged the enterprises to strengthen what they already had, to improve techniques, and to improve management. More and more of the products of local Sichuan industry are beginning to find their own places in competition throughout the country.

Competition has appeared among enterprises under the socialist system of ownership by all the people and has obtained a positive economic result, so it cannot make people wonder whether competition is after all a peculiar economic phenomenon of capitalism, or whether these conditions do exist in socialist production forms. Our country's economic academic circles have come to the conclusion, on the basis of an examination of the history of commodity production, that competition is not associated only with capitalism, but that it is associated with the production of commodities. Where there is commodity production there is competition. In the history of human society there have been small commodity producers, capitalist production of commodities, and socialist production of commodities, so there is competition under small commodity production conditions, capitalist commodity production conditions, and socialist commodity production conditions. Since our country's economy is a socialist, planned commodity economy, the appearance of competition cannot be avoided. However, competition under socialist conditions is not the same as competition under capitalist conditions. Capitalist competition is established on the foundation of the system of private ownership, and it represents competition of conflict between the fundamental interests of capitalists. Competition is like a merciless whip, constantly urging the advance of technology, while at the same time creating an anarchic situation for the development of production, the failure of enterprises, the loss of jobs by workers, and other results. Socialist competition, however, is established on the foundation of the system of public ownership, and it represents a competition of unanimity of the fundamental interests of socialist enterprises. We are completely capable of consciously mastering the laws and, under the direction and control of the plan, eliminating those negative aspects, and retaining and developing the positive. Therefore, socialism certainly does not exclude competition but instead should propagandize the "protecting of competition." This is just what our government is presently doing.

Competition between Sichuan enterprises is drawn from two specific factors. One is a market where supply exceed demand, and the second is that enterprises have independent economic benefits. The second factor is obvious. If an enterprise does not have independent economic benefits but eats from the big pot, it loses their internal motivation for competition. The problem lies in the first factor. In the economic life of our country, there is no question but that there has long been a situation whereby supply have been unable to meet demand, both in the means of production and in consumer goods; sellers of products have been in an advantageous position, while consumers (including consumers of the means of production) have had no alternative choice with regard to most products. "The daughter of the emperor need not worry about finding a husband," and so naturally there could not be any competition between production enterprises. Since last year our country has carried out a readjustment of the national economy, and a situation of supply exceeding demand has developed with regard to some commodities, giving consumers the possibility of a choice with regard to those commodities. The consumers' choice is merciless. This kind of choice is really an evaluation and a reward or penalty for the results of an enterprise's production management. Under such circumstances, the advantageous position devolves to the consumer, forcing the productive enterprise to develop competition in a struggle for the consumer market. As a result, social requirements are satisfied and the economic results for the whole society are improved. It should be pointed out that although a market in which supply exceeds demand is a condition for the formation of competition, the process of supply exceeding demand must be controlled. As for the measures that would be appropriate, this can be regulated by economic organs through the plan and through various kinds of economic levers.

Along with the expansion of competition and enterprise authority to make their own decisions, enterprises have begun to break through the boundaries of trade, territory, and system of ownership and to establish direct lateral realtionships between industrial enterprises, between industrial enterprises and commercial enterprises, between industrial enterprises and agricultural enterprises, between civilian and military industrial enterprises, and between industrial enterprises and scientific research organs, giving rise to many kinds and forms of professional cooperation and joint bodies. Of these, there are joint producers' bodies for joint cooperation in turning out a given product, joint marketing bodies for the joint marketing of products, joint product research bodies for joint cooperation in carrying out the development of new products and new technologies, and agricultural-industrial, or agricultural-commercial bodies for the processing of subsidiary agricultural products. In every kind of joint economic body, there is some process of concentration of production or concentration of capital that has not come to the people's attention, and the professional cooperation and union have given rise to a noticeable new production force. Capitalist professional cooperation and alliances developed out of competition. Free competition elicits a concentration of production and concentration of capital, and when that concentration reaches a certain stage, it produces monopoly, the emergence of alliances of medium and small enterprises, and the annexation of medium and small enterprises by large enterprises, producing trusts, cartels, concerns, and other such monopolistic special cooperation and joint organizations. Will professional cooperation and alliances follow this same route under socialist conditions? Of course not. Because we have a socialist planned economy, the organization of various kinds of joint economic bodies can constitute a unified program, a rational arrangement, and can be carried on step by step in a planned way. However, in the same way, it is impossible to avoid competition within certain limits. Because we can produce only an internal requirement for professional cooperation and alliances by developing competition between enterprises, that alliance can succeed only when the economic benefit of the enterprises is protected and expanded under professional cooperation and alliance. If it is not like this, under circumstances rather in which the enterprises have not felt this need, even to the injury of their interests, joint economic bodies can be forced upon the enterprises by administrative order, but such alliances would only be one of form. We have had this lesson.

Expansion of the authority of an enterprise to make its own decisions brings with it the corresponding problem of who is to make policy on the important questions concerning the enterprise. Our enterprises are socialist enterprises, and from the standpoint of theory it of course is the workers who shoud be the masters in their own house. However, since the enterprise has no authority to make its own decisions, although one may say that the workers are participating in management, they are actually being allowed to complete the tasks that have been handed down by their superiors; they are certainly not taking part in making policy for any of the enterprise's important questions. Expansion of the enterprise's authority to make its own decisions solves the problem of the enterprise having or lacking authority, but after it has the authority, the question of who will exercise it has still not been answered. One of the important questions here is that we must clarify and solve the relationship between enterprise management and the workers. In some socialist countries, there is still a kind of subordinate relationship between management and the workers, and the operating situation of the enterprise is always determined by the management. Yugoslavia practices worker autonomy, and management is responsible to the workers' committee. Starting from the actual situation in China, in some enterprises we conducted experiments making employee representative congresses the highest organ of authority in the enterprise and gradually developed management through election by the employees' congress, with simultaneous appointment by the state. Thus, management was responsible to the employees' congress and also responsible to the state. The employees' congress made policy regarding important questions of the enterprise, and management participated in the whole policy making process and also implemented the resolutions of the employees' congress. This kind of policy making system seems to be more suitable to the present reality of China's enterprises.

In the foregoing we have briefly related several aspects of the Sichuan experiment in the reform of China's economic system. These reforms gave the Sichuan economy a strength it has not had before. Comparing 1979 with 1978, in 84 local industrial enterprises out of the 100 experimental enterprise units, gross product value increased by 14.9 percent and profits turned over to the state increased 24.2 percent--figures higher than those in enterprises not involved in the experiment. In 1980, five enterprises experimentally taking responsibility for profit and loss displayed new vitality. Compared to 1979, their gross product value increased 41.2 percent, profits increased 81.7 percent, and collection of revenues turned over to the state increased 47.6 percent. In industries experimentally retaining a portion of the profits, the rate of economic growth was not as great as in 1979 because of adjustments to the national economy, increased prices of some raw materials, reduced prices of some products, and a general increase in employees' wages. There were, however, striking advances in improved quality, improved economic benefits, reform of the product structure, increased social wealth, and satisfied consumers. This is a complete turnaround from what was required by our former route of economic development of heavy capital construction, light production, high accumulation, and low efficiency. In addition, there was unprecedented progress in matters of the collective welfare of the enterprises, particularly with regard to housing construction, and there were relatively large increases in the income of individual workers. A point was proposed here: The results of the reform of the economic system should not be measured simply by the rate of economic growth for a given time, but should be measured by the degree to which they satisfy the needs of consumers. We should also consider that expansion of the authority of enterprises to make their own decisions transforms enterprises from "beads of the abacus" into organisms with great vitality that can propagate themselves, gives employees real content and a material base for being masters in their own homes, and provides a vast world for the full development of talent among leading cadres, managers, and technical personnel. These changes have more far-reaching significance than any increase in economic results for a single period.

Of course, the past 2 years of experiments in reform of the sytem in Sichuan have not all been smooth sailing. Because of contradictions between new systems that had already been reformed and old systems that had not yet been reformed, contradictions between adjustment and reform, etc., our reforms could not help being faced with many complications and difficulties. However, we have already basically determined the general direction of the reform, that is: to consciously employ economic laws according to the requirements for developing a commodity economy and encouraging the socialization of large production, under conditions whereby the dominant position of the system of public ownership of the means of production would be maintained; to transform the system of highly centralized state policy making to a system of combined policy making by the state, the economic units, and the individual workers; to transform the simple plan regulation to full development of the effect of market regulation under the guidance of the plan; and to transform management of the economy through administrative methods to management of the economy principally through economic organization, economic methods, and economic laws. Therefore we are fully able to resolve these contradictions by summarizing the economic lessons of our experiments in the guidance of the general direction, we are fully able to continue to proceed with the reform experiments in the midst of economic adjustment.

At present, an extraordinarily important problem posed in the course of practice is: when the reforms produced by the expansion of the authority of enterprises to make their own decisions reach a certain point, we must have a further solution of the question of how to strengthen the plan guidance of the whole national economy under the new conditions of market regulation entering into economic life, and to combine planning closely with the market.

The expansion of the authority of an enterprise to make its own decisions and the implementation of market regulation have a positive effect on motivating that enterprise to increase production of products suitable to the market, and on improving economic results, in order to achieve the socialist production targets and satisfy the material, cutlural, and livelihood needs of members of the whole society. However, when state-operated enterprises are relatively independent commodity producers, retain a portion of the profits, and especially take responsibility for profit and loss, the quality of management and the amount of profit have a direct effect on the vital interests of the enterprise and its employees. Therefore, they must not only consider the needs of the whole society in their production management, but they must also consider the interests of the enterprise itself. So, an enterprise might easily develop contradictions with the requirements for the development of the whole national economy in the direction of its production management, in decision to utilize capital is has raised for itself to expand re-production, or in the allocation of bonuses; it might cause redundant production or redundant construction to occur; or it might award bonuses indiscriminately. We are presently encountering these problems. However, the method of solving them is definitely not to hobble the production management activities of an enterprise, but to strengthen planning guidance from a larger angle while continuing to enliven that enterprise, and to combine the interests of that enterprise with the interests of the whole society. For example: an enterprise can carry out production management activities on its own, but it cannot change the production direction formulated by the state for that enterprise, and it must accept state orders for goods and complete the state plan. An enterprise can utilize capital it has raised itself in expanding re-production closely related to simple re-production, but the direction of investment must match the requirements of national development and must undergo comprehensive assessment and approval by state planning organs. Under profitable circumstances, an enterprise can award additional bonuses to its employees or promote them to higher wage levels, but these may not exceed the range of increase specified by the state for total wages. There must be a multichannel circulation for both means of production and consumer materials, and an enterprise can sell a portion of its product itself, but state-operated materials enterprises and commercial enterprises should always be the main bodies of the various kinds of circulation channels. In short, an enterprise's production management activities must satisfy these two conditions: they must suit that enterprise's own economic interests, and they must also suit the requirements of national economic development.

Solutions to the foregoing several problems are easy to talk of but extremely difficult to carry out. We must formulate correct policies, adopt appropriate economic methods, and conduct strict economic legislation and economic supervision to be able to achieve them. In the relationship between planning and the market, market regulation is like a fine horse, and planning guidance is the rider controlling this horse. What we need in a rider is this: although he cannot beat the horse to death, neither can he let it go uncontrolled, allowing it to become a wild horse without reins, running wildly everywhere; he must control it while advancing along the track of socialism. This is a kind of driving skill for controlling a commodity economy under the socialist system. Learning this kind of driving skill is difficult, but it must be learned, for otherwise we will have no way to maintain the correct direction or to realize the objectives of reform of the economic system.

In the midst of the reform experiments, we solved the problem concerning what relatively independent economic interests an enterprise under the system of ownership by all the people should have and we devised and tried several forms of allocation of profit between state and enterprise; all of this constituted a great breakthrough in both theory and practice. If an enterprise has its own economic interests, it will have an internal economic motivation, and the whole economy will have vitality. However, just as can happen in the development of any matter, no sooner are old contradictions resolved than new problems arise. For its own development and growth, an enterprise must always increase the proportion of profit retained; however, state finance departments are then afraid that the enterprise will get more and reduce the income of public finance. These contradictions tell us that it is not enough just to acknowledge that enterprises under the system of ownership by all the people ought to have relatively independent economic interests. We must formulate rational restrictions on the amounts of profit allocations between state and enterprise. Speaking concretely, even after an enterprise has been changed from the system of uniform receipts and expenditures to retention of a percentage of profit or responsibility for profit and loss, there must be a clear delineation as to what portion of the simple receipts that is has created should be concentrated with the state and what portion retained by the enterprise, as well as which expenditures will be taken care of by the state and which expenditures are the responsibility of the enterprise. This should all be done so as to guarantee the the primacy of the state's interest and also guarantee a reasonable interest for the enterprise.

On the basis of these requirements, we suppose that under conditions where an enterprise is responsible for profit and loss, expenses for maintaining simple re-production, expenses for carrying out expansion of re-production closely connected to simple re-producttion, expenses for conducting matters relating to employee' collective welfare, and employees' wages and bonuses can all be considered to be paid by that enterprise. To encourage the activism of the enterprise it should retain a part of the profit obtained as a result of improved production and economic management. The actual method of allocation should be: the above-listed items should first be deducted from the net income of the enterprise, and the portion that is left will be subject to the collection of industrial and commercial tax, income tax, fixed asset tax, resource tax, and other various kinds of taxes that will be paid over to the state. Having gone through this distribution, how much of the net income created by an enterprise will be given over to the state and how much retained by the enterprise will emerge as a rough proportion. Judging by recent circumstances, the size of the ratio of profit retained by the enterprise is limited only by whether or not public finance is able to recoup from the increase in enterprise profit for that year. Only in this way will the reform of the economic system be able to develop healthily within a stable increase in state finance receipts or under conditions where, although receipts do not increase, disbursements are correspondingly reduced.

On problems related to economic interests, besides the contradiction between state and enterprise, contradictions have also appeared between one enterprise and another. In the past the profit of each enterprise, no matter hwo large or small, was all turned over to the state, so there were no differences in interest between enterprises. Since the reform, however, the income of an enterprise has been shifted to how much profit that enterprise makes, and the differnces between enterprises have vecome evident. This illustrates a condition that we often refer to as "hardship and happiness are not divided equal." There are subjective reasons and objective reasons for hardship and happiness being unequally divided and what we will discuss here are the unequal objective conditions of enterprises that result in that inequality of hardship and happiness--such as prices not being set rationally enough, great differences in the level of technical equipment, different degrees of abundance or lack of natural resources, etc. Because, on the one hand, objective conditions are unequal, but, on the other hand the same yardstick is used to measure enterprises economic results, using a single ratio to recover profit for retention gives those enterprises with the best objective conditions an excess profit that they did nothing to create; in the case of other enterprises, disadvantageous external conditions may cause them to go uncompensated for their efforts. These irrational circumstances have a serious influence on the activism of some enterprises and weaken the effects of the reform. We are now striving to change such kinds of circumstances. Practice tells us that the creation of external conditions that are for the most part objectively equal for the enterprises is a basic requirement for the implementation of reform of the economic system. Moreover, this requirement can be realized only in the midst of reform, and the most important part of this is reform of the price structure and the tax system. Reform of prices is extraordinarily difficult, however, and with our country presently in a period of economic adjustment we should be even more prudent. Under these circumstances, we must find some interim method to solve the probelm of the unequal division of hardship and happiness in the economic interests of enterprises.

The economic management system is an integral whole, and the production, circulation, distribution, and consumption systems, etc., are each one aspect of this whole. Moreover, they are linked to one another. They combine in a network that is difficult to loosen or to separate. When you pull one link, it moves everything. Because of this, the reform of the economic system must be linked to form a whole. It will not do to simply conduct a reform of one aspect. The 2-year reform experiment in Sichuan was like this: starting with the expansion of an enterprise's authority to make its own decisions, the reform of several aspects, production, circulation, and distribution, was conducted in mutual combination. Of these aspects, distribution is the core of reform, for without reform of distribution, other reforms are meaningless. Moreover, without reform of production, circulation, etc., reform of distribution cannot be effected. There is one view that says that the reform of a country's economic system must be "complete" and "simultaneous"; otherwise there is little chance for success. Reform of enterprise management can be conducted only after the external conditions of the enterprise have been provided for; otherwise it will create confusion. For this reason, reforms must begin with the formulation of a complete, overall program, and after formation of the program, it should be implemented simultaneously, in every area, throughout the country. There is a certain sense to this viewpoint. Without experimental reform of a part, however, the complete overall reform program will not be successful. In a country like ours of almost 1 billion people, there is no way to implement reform simultaneously throughout the country, even if we begin very early in the morning. Therefore, under conditions in which the overall program has not yet been designed, the reform can first consider small systems, later medium-size systems, and finally big systems. In the plan carried out in Sichuan, beginning with the expansion of the authority of enterprises to make their own decisions, the reform of materials, commercial, and finance organizations was in reality a small system. The later implementation of enterprise responsibility for profit and loss, with the need to carry out simultaneous reform of the price structure, the tax structure, and other aspects, could be a medium-size system. Finally, enterprises still had to be liberated from departmental and district subordination and conduct economic management independently, requiring simultaneous reform of the whole economic guidance arrangement; this could be a kind of large system. In short, it will not do to carry out reform except by systems, but neither will it do to make further changes once a system is complete. The complete reform program includes the theory of reform and the direction dictated by principles, the specific requirement for reforming each kind of organization, as well as the procedures, forms, and methods for implementing the reforms. These are all necessary to for successful reform, but this kind of program must start with the realities of our country and be truly a Chinese type. The procedure, form, and methods of implementation must be positive and safe, and be a gradual transition, to ensure that every reform measure will have a positive effect on the development of production.

The Sichuan experiment in reform was carried out in the midst of our county's readjustment of the national economy. Economic readjustment has destroyed some of the shortage situations that have existed for a long time, whereby the supply of commodities fails to meet demand, and has made it possible to employ the market mechanism to develop competition in economic reform. However, because of the economic readjustment, the production tasks of some enterprises were inadequate, and there was no way to implement the reform. At present, it is absolutely necessary that readjustment be the central task of our national economy and that reform serve readjustment; otherwise there will be no way to overcome the serious difficulties facing our economy.

Taking the long-range view of the problem, however, the fundamental solution for our economic development still lies in reform. The present readjustment is for the sake of establishing the conditions for complete reform in the future. One view is that we carried out readjustment because reform is wrong, but this is completely erroneous. There is nothing wrong with reform. If it had not been for the reforms of the past 2 years, we would not have the present good situation. On the contrary, because of the influence of long-time "leftist" errors in economic work and mistakes in economic policymaking, there has been a serious proportional dislocation influencing the reform. There is also the view that with readjustment as the central task, we should not carry out reform; this too is incorrect. Some reforms might influence the readjustment, but will on the contrary advance it, and some readjustmants could not have any beneficial result without undergoing reform. Therefore, in the readjustment, all reforms beneficial to the readjustment must be carried out actively, so as to encourage readjustment through reform.

At present, the reforms we are emphasizing are: While continuing to revitalize the microeconomy, strengthen plan guidance for the macroeconomy. This is completely consistent with the centralization and unification required by the readjustment. Utilize advantageous opportunities in the readjustment to accelerate the pace of professional cooperation and association. It is perfectly possible to combine this with the closing down and simultaneous shifting of some enterprises. Actively advance the internal reform of the enterprise, the reform of the product structure, and the reform of the guidance system, for this is what is required by the transformation of our production and construction policy, Carry out experiments in responsibility for profit and loss within a certain sphere, and obtain even better experience, as is required to prepare for the adoption of future new reform procedures.

Reform of the economic system is where our hopes for carrying out the four modernizations lie. The experiment in reform of the Sichuan economic system will move forward unswervingly.

FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

ECONOMIC JOURNAL ON IMPROVING ENTERPRISE MANAGEMENT

HK100314 Beijing JINGJI GUANLI [ECONOMIC MANAGEMENT] in Chinese No 6, 15 Jun 81 pp 29-32

[Article by the Chegdu measuring instruments and cutting tool plant: "On Further Improving the Management and Administration of Enterprises in the Course of Readjustment"--slantlines denote boldface type]

[Text] It was in 1979 that our plant first began to expand its autonomy on a trial-point basis. Since then we have enjoyed varying degrees of autonomy in the six different sectors of personnel, finance, resources, supply, production and marketing. The autonomy served as the motive power for us to arouse the enthusiasm of the workers, promote the development of production, enliven our economy and raise our management and operation to a new high level. Over the past 2 years, we have objectively grasped the following:

/1. Enforcement of an economic contract system within plants./

Following the expansion of our autonomy, we enforced an economic contract system within the plant, based on the characteristics of our production operation activities. The contractual requirements specified that the workshops carry-out "four fixes" and "three guarantees," namely, fixed personnel, fixed machine tools, fixed average working hours' remuneration for advanced workers and fixed production time and production quantity; and guaranteed product variety and specifications, guaranteed product quality and quantity and guaranteed profits. The functional section also imposed on the workshops a system of "10 responsibilities." The responsibilities were for: supply of raw materials and subsidiary materials; supply of workshop equipment; repairs and upkeep of equipment; accuracy and completeness of specifications for products; accuracy, completeness and available use of all technological documents; supply of electricity, water, air and gas; suitable deployment of manpower and punctual availability of fixed working hours; timely issuance of production plans and instructions; provision of safety protection equipment and measures; and timely inspection of the production process and final inspection of the product. Awards were also fixed for overfulfillment of contractual tasks; while for failure to fulfill contractual tasks, penalties according to a fixed schedule are made and those responsible for heavy economic losses are severely punished. These measures ensure the smooth fulfillment of contractual obligations.

The implementation of the economic contract system within plants had changed the administrative relations and service relations between the sections or offices and the workshops and between the supplementary workshop and principal production workshop into economic relations. It has strengthened the sense of responsibility on the part of the workshops, sections and offices of the plant. For example, in the past when there was some trouble with the supply of electricity to the production sector, it could be left unattended to for some time even though the cause was one arising within the plant. But with the economic contract system within plants in force, the rule is that any such incident should be settled within half an hour. Even if the cause is an external one and cannot be fixed immediately, some measure must be brought up to deal with it, otherwise the party concerned will have to bear the economic responsibility. This has forced the plant's motive-power section to be constantly on the watch over the electricity supply system, frequently inspecting it and keeping it in good repair. In the case of trouble, it is attended to at once irrespective of the weather conditions. In this way, the implementation of the economic contract system within plants means the simplification of the procedure of control on the part of the plant's principal administrative section. On the one hand, the workshops are responsible for the economic effects of their operations and on the other hand the functional section or office must provide the necessary production conditions for the workshops. The responsibilities of both sides are clearly marked and there is a basis for making either penalties or awards. In turn, the planned character and serene nature of the economic work of the enterprises is augmented, the efficiency of production organization work is raised, and the normal progress and development of production is ensured.

/2. Implementation of an internal economic accounting system and formulation methods of distribution in accordance with reality./

The workshop is the basic unit for the organization of production within an enterprise. In enforcing relatively independent economic accounting methods in the workshops, sections and offices, we have closely knitted together the relationship between the workshop's authority, responsibility and profits and the economic effect and this in turn has aroused the enthusiasm of the workshop and strengthened the management and operation of the enterprise. The independent accounting in our workshops, sections and offices is carried out under the principles of a unified plan, unified fixed quotas, unified prices, unified tax rates and profits, and a unified method applicable to the plant as a whole. 1) All products of the workshops, sections and offices are regarded as commodities for which accounting and planning of one's own profits and losses is carried out. 2) Business transactions within the plant are settled or transferred as normal debit or credit entries in accordance with the internally planned prices. 3) The former practice of charging losses due to stockpiling and extravagance to the gross production cost has been changed to hold the workshops, sections and offices individually responsible. Losses arising out of rejection due to quality problems are charged to the production cost of the production workshop. 4) Fixed assets and circulation capital used by the workshops, sections and offices are all treated as compensatory, or uses requiring compensation. Thus, to make the workshops, sections and offices strengthen control of their funds and to avoid state funds lying idle or being wasted, the rule is that the workshops, sections and offices should pay to the plant a "tax levy" on the use of the fixed assets and also pay interest on the circulation funds held (2.1 per mill within the norm; 4.2 per mill above the norm; and 8.4 per mill for withholding or allowing an excessive amount to lie idle). In this way, the departments concerned are forced to make effective use of the equipment and funds and curtail their withholding or waste of funds.

The implementation of independent accounting has produced clear-cut economic results. Take, for example, the case of equipment sealed for safekeeping and reducing expenditure. In 1979, the value of equipment sealed for safekeeping was 1.88 million yuan whereas in 1980 it was found to have reached 2.18 million yuan. In former years, external printing expenses had amounted to 80,000 to 90,000 yuan a year but in 1980 the actual amount expended on them was only 10,000 yuan. In order to strengthen the accounting of the workshops' production results and to ensure the marketability of the products, we enforce the ruling that the value of products of which there is a glut produced by the workshops outside the plant's plan should not be counted but the production cost should be counted and in addition that the workshops should bear the economic burden for any stockpiling or funds that lie idle on account of this phase of the output. An interest payment of 4.2 per mill is charged for withholding funds from use and additionally a management fee must be paid. The purpose of this is to make two workshops refrain from engaging in production blindly and make them pay due attention to the requirements of the market. In the past, the supplementary workshop bore no economic burden for the production of rejects and the production cost of such rejects was lumped on the production workshop. Economic accounting now rules that each must take care of its accounts separately and each must bear its own economic responsibility. This has forced the supplementary workshops to strengthen their management and control, to pay due attention to the quality of the products, and to do their utmost not to turn out rejects or substandard products.

To enable the rigid enforcement of economic accounting, we have also provided the workshops, sections and offices with certain economic power. This gives the workshops (sections and offices) the power, on the logical premise of first ensuring the fulfillment of the plant's entire plan and subject to the approval of the production section, based on the demands of the market, to organize the production of additional products or to offer labor and services to society. With regard to the newly added and marketable products, the workshops are entitled to retain within a specified period a rather high proportion of the gross profits as a foundation fund for future development of production. The workshops are given the authority to determine the distribution of the foundation fund. In addition to distributing it to their various sections or directly to the workers on the basis of the conditions upon inspection of the fulfillment of the targets, they have the authority to retain a small portion of the funds to serve as special awards or as subsidies to the employees and workers in need.

Based on the independent economic accounting provisions for the workshops, sections and offices, regulations covering the conferment of awards have been formulated. In 1979 we adopted the method of distributing the award funds which were made up of the "basic awards" plus an award for exceeding the planned profits. This method was meant to make use of economic benefits to eradicate the past one-sided trend of simply seeking value and quantity in production, disregarding the waste of raw materials, and disregarding the economic effect. At the same time, the good or bad performance in the management and operation of the workshops directly influenced the amount of funds available for making awards. In 1980, we took a step further to improve the method of distribution and adopted one calling for the percentile distribution or retention of a percentage of the gross profits from each month's production from the production workshops; the supplementary workshop can retain a percentage of the gross amount of reductions on the production cost; while the functional section or office can set aside funds for a sinking fund on the basis of the gross amount of profits from the sales volume of the current month. To solve the contradiction arising out of the failure to abide by the principle of more work more pay due to the fact that prices do not always coincide with actual value, we have adopted remedial measures which, when determining the percentage ratios due to the various workshops, take into account the requirements of society and the actual benefits received by the workshops. In addition, concerning cases in which changes in the structure of commodities has brought about diminishing sales and considerable reductions in profits in comparison with usual practice in the past, the workshops concerned are given some form of compensation in respect of their products which are in short supply subject to the provision that this has no effect on the gross sinking fund available for distribution. Moreover, in business accounting this year an item under the heading of working hours has been added. This has helped to solve the problem of disparity of joy and hardship in the percentile distribution or retention. It makes the distribution of the benefits more rational.

/3. Firmly implement the party's policies and arouse the enthusiasm of all types of personnel./

Following the expansion of autonomy, enterprises have a certain amount of power concerning the appointment or dismissal of personnel. Over the past few years, we have exercised this power in connection with the appointment and dismissal of our middle level cadres. We have selected a batch of young and healthy people to fill the posts of cadres of middle level or above. The original team of leadership cadres of middle-level or above has been reshuffled and replenished. In particular, we have made special efforts to appoint engineering and technological personnel who are good in organization and leadership work to fill leadership posts at various levels and encourage them to give full play to their talents. The selection of young and strong engineering and technological personnel to strengthen the leadership circle produced the effect of arousing the enthusiasm of the engineering and technological personnel, making the team of cadres young and energetic, specialized, intelligent and well informed, and promoting technological renovation and technological restructuring work in the enterprise.

/4. Cultivating the operational ideology and opening up wide the road to production and marketing./

Following the expansion of autonomy, it is obvious that with the increase of revenue to the state as a prerequisite, whether or not it is possible for the group to be more benefitted and the individual to receive more income depends entirely on whether more profit can be made which in turn depends on increased production and increased sales. In 1979, production orders from the state amounted to only 16 million yuan, or roughly 30 percent of the gross value of the plant's annual output. In 1980, these orders amounted to only 18.5 million yuan, or 38 percent of the gross value of the plant's annual output. This year, there were no such orders from the state at all. As a matter of fact, with the economic readjustment work in progress, the whole machine building industry is short of production orders.

For our part, there is now a glut of many of our major products which we can produce on a large-scale basis. But what the market actually needs is products that are in short supply. Our production of this category of products is small and besides, the required skills to produce them are rather complicated while the production cost is high. Moreover, with regard to the sale of these products competition from our contemporaries is keen. However, on account of our expansion of autonomy, we have taken up the burden of looking out for our own interests. We have decided on the policy of shaping production according to market demand. For example, the workshop turning out percentage meters has found that the market cannot absorb more of this product and its sales have slackened. Accordingly, it has turned to producing new products which its present equipment and technology can easily handle, such as tools for measuring the changes in position of the ceilings of mining tunnels, measuring tools for wheels of railway wagons, leather meters and so on. The workshop making drills and screws has boldly reformed its skills, readjusted the load capacity of its equipment, and is turning out hand-operated drills in quantity and has managed to change losses into profits in the manufacture of this item. This has fulfilled market needs and the workshop has found a way out even in the face of severe competition. Some of the workshops have learned the special needs of certain users and have undertaken to turn out special products complying with the customers' specifications. Some workshops even go so far as to produce goods at the customer's request, goods which provide a slim profit margin but involve a high labor cost. In sales and marketing, we pay special attention to making market forecasts. We augment our sales services and build up special sales relationships. We hold sales sessions to solicit orders and engage in much sales propaganda work for the products, in an endeavor to promote direct sales by ourselves. To increase the competitiveness of our products, we have reinforced the work on quality control. In the manufacturing process, starting from the receipt of the raw materials and ending with the end-products coming onto the market, each and every step on procedure is subject to rigorous quality control, and very commendable results have been achieved. For example, our straight-handle twist drill bit and percentage measuring meters have been awarded by the state with a gold badge and a silver badge respectively, while six of our major products have been acknowledged by the First Ministry of Machine Building as "products of reliable quality." This year, altogether 12 varieties with some 190 specifications of products have been sold to some 10 countries and areas in America and Europe. The gross value of the volume of sales reached 10.3 million yuan. Since the expansion of our autonomy, despite the steadily diminishing orders from the state, our direct sales have been steadily increasing. Last year, not only were all the products that year sold out but also some 2 million yuan worth of quality products which had been stockpiled in the warehouses were sold.

/5. Tap potential, renovate and restructure, and expand the production capacity of products in short supply./

What is stated below also illustrates the motivation provided to us by the expansion of our autonomy. Over the past 2 years, we have made use of the financial power and material resources derived from this source to newly build a workshop and an oxygen and nitrogen chemical section which have greatly helped to improve the quality of our products. We have also expanded the workshop for making straight-handle drill bits and taper-handle drill bits and the area of the compound for making gauge blocks. The cost of expanding the workshop for making the straight-handle drill bits reached nearly 600,000 yuan, but the production capacity of the workshop was thus increased from 18 million sets originally to 30 million sets now. At an average profit margin of 0.19 yuan per set, the entire investment cost can be recovered within half a year, if the production capacity develops normally. In addition, we have taken note of the actual market needs, tapped our production potential and increased the output of products which were in short supply. For example, last year we put into production articles which had been scantily produced before such as broad-angle squares, standard-angle squares, lever micrometers of 1/1000th scale, and lever micrometer callipers. We also actively trial-produced other new products and improved on certain old and established products.

/6. Strengthen political and ideological work and correctly handle the three "three-in-one combinations."/

After the expansion of our autonomy, in addition to making use of material benefits to arouse the enthusiasm of each unit and the staff and workers of the plant, we have also laid special emphasis on political and ideological work for each person and taken political and ideological work as an important constituent part of enterprise management which must be knitted together with modernized production. Since the expansion of our autonomy, we have started to arouse the enthusiasm of the individual and in ideological education, we have paid special attention to correctly handling the relations between the three "three-in-one combinations," namely, 1) relations between economic measures, political work and administrative measures; 2) relations between power, responsibility and benefit; and 3) relationships between the state, the collective and the individual. We believe that the expansion of enterprise autonomy is an economic measure to arouse the enthusiasm of the people, but an economic measure cannot replace political and ideological work or the necessary administrative control. Hence, while firmly insisting on the principle of material benefits, we simultaneously emphasize the full display of the demeanor of communism and have organized a labor production emulation campaign for the entire plant and also an eight-team competition among the sections and offices. We urge making contributions to the four modernization and by means of public appraisal, have chosen pacesetters to pursue this objective. We realize that in strengthening our political and ideological work we should not overlook the need to give the necessary administrative directives otherwise it is not possible to complete the entire task.

In our political and ideological work, we make our staff and workers understand, and correctly assess, the relations of interest between the state, the collective and the individual. After having fixed the tasks for the entire plant this year, we have suggested to the staff the following targets: the profit remittances to the state this year should reach 17 million yuan; the amount retained by the plant should be 3.06 million yuan; and concrete arrangements should be made for the portions available for rewards such as building staff dormitories and collective welfare work. At the same time, it has been strongly pointed out that to achieve the objective of remitting 17 million yuan to the treasury, the gross value of output should reach 52 million yuan and that to justify a retention of 3.06 million yuan, the profits must reach 17 million yuan. This is to make the staff understand that only when the interests of the state have been taken into account can there be benefits for the collective and for the individual. As for the correct handling of the relations between power, responsibility and benefit, it has been especially emphasized that we should not merely talk about benefit and neglect responsibility but that on the basis of a definite amount of authority, there must first be a sense of responsibility. It has further been stressed that expanding autonomy is not tantamount to increasing monetary income but rather increases responsibility. Accordingly, we have adopted the following principle: that economic benefits are determined by the economic effects while economic effects are in turn determined by economic responsibility. We demand that each and every level should be held responsible and that for each and every job there must be someone responsible.

Summarizing the above, it has been found that under the direct leadership of the provincial and municipal party committees the expansion of our plant's autonomy has progressed relatively smoothly and achieved rather obvious economic results. Take for example the profit remittances to the treasury. In 1978, before the expansion of our autonomy, our profit remittances to the treasury amounted to 13.5 million yuan. In 1979, the year when the autonomy of our plant was first expanded, it rose to 17 million yuan, a net increase of 3.5 million yuan. In 1980, the readjustment of the national economy was in progress and as a result the whole machine building industry was in a state of "operating below capacity," but because of the expansion of autonomy, the profits were still found to be 14.5 million yuan, a net increase of 1 million yuan over 1978 when the expansion of autonomy had not yet been implemented. These statistics clearly indicate that the expansion of the plant's autonomy has brought about new changes in the management and operation of the enterprise. It has instilled new vitality into the enterprise unit and helped the enterprise to raise its economic efficiency. Great prospects for future development are thus envisaged.

Nevertheless, a review of the work on expansion of autonomy conducted over the past 2 years has revealed the emergence of many problems. Some of these problems have arisen because ideologically we have fallen behind and because while even better results could have been reaped, we have failed to realize them. More importantly, objectively speaking, certain regulations at present are restricting the fruitful results of the expansion of autonomy. If these problems are not solved then the reform of the economic structure cannot be penetratingly carried out and effects of the expansion of autonomy cannot be augmented or attain great development.

In order to push further the expansion of enterprise autonomy, first of all we should further arouse the enthusiasm of the people. We should provide the enterprises with more of the necessary power of handling personnel. They must be given greater authority on such matters as staff remuneration, appointment and dismissal.

Originally, the expansion of autonomy concerned profit distribution (percentile retention of profits) and what principally affected the individual was the matter of awards. But speaking from the standpoint of material measures, depending on making awards alone is not sufficient. As a matter of fact, at present, due to the combination of various factors, enterprises which have produced good economic results are not necessarily in a better position in the matter of awards than those enterprises which have produced good economic results are not necessarily in a better position in the matter of awards than those enterprises which have put on a poor performance. Moreover, the state has enforced certain regulations covering awards with the result that the distribution of awards has tended to become more or less equalized.

In our opinion, to solve this problem we should endeavor to allow the scale of salary and wages to reflect the caliber of the management and operation of an enterprise and the economic effect. Unfortunately, the present system of the state exercising unified control over salaries and wages is out of joint with, and even runs contrary to the operating conditions of an enterprise. If an enterprise has the power to determine the increase or decrease in the salary and wages of the staff members, then it will be possible to make better use of material benefits to arouse the enthusiasm of the individual. It will also be possible to greatly increase work efficiency and eradicate such phenomena as overstaffing and irresponsibility.

An enterprise must also have the power to cut down redundant personnel, as a measure to increase its economic effect. At present, the enterprises appear to have a rather large number of redundant personnel whose existence objectively speaking restricts the raising of the labor efficiency rate. Naturally, suitable arrangements must be made for those personnel relieved of their posts and we should be careful not to create any serious social problems in this connection.

Second, from the macroscopic point of view we must now endeavor to strengthen the leadership work over the autonomy of enterprises and through the adoption of a sound economic policy determine which type of enterprise to support and which to restrict. We must refrain from the former practice of the departments in control making all the concrete production plans for the enterprise units. In our opinion, with the expansion of autonomy on the part of the enterprises, more rigid and higher demands must be made of the departments in control. Perhaps it may be appropriate to describe the work expected of them with the following words: "service, overall planning, coordination and supervision."

Third, an economic ordinance must be formulated and also concrete policies and measures must be formulated which are in line with the guiding principles. Concretely speaking, 1) A unified statute (basic law) covering industry must be instituted. The establishment of a plant must strictly abide by existing laws and regulations. Violations should be prosecuted by law. 2) With regard to which products are to be promoted and which are to be restricted, we should so regulate them by means of price variations. Economically, we should restrict the production of goods the sales of which are stagnant and that will ultimately be stockpiled. For the blind production of goods resulting in economic losses, the responsible persons must bear the economic burden. 3) The quality standards of the products must be strictly implemented. There should be no production of goods whose quality is not up to specifications and any such goods produced should not be put on sale. Enterprises turning out sub-standard goods should bear the economic responsibility for them. 4) The use of funds must be kept under strict control. Banks must be allowed to exercise their power of independently supervising and controlling the use of funds. They should have the power to stop further loans to, or impose heavy interest rate on, enterprises which have retained for their own use funds in excess of the limit. 5) A law of contracts must be instituted. All enterprises and government industrial departments must be governed by this law of contracts and bear the relevant economic responsibility.

By means of economic legislation and appropriate economic measures, we can avoid all unnecessary interference and place the enterprises truly in the position of relatively independent producers of commodities, and make them treasure such a position for the sake of their own interests. In this way, the state will be able to smoothly make the enterprises obedient to the central task of readjustment and to enable the reform of the economic structure to progress smoothly.

FINANCE AND BANKING

ROLE OF FINANCE, TAX SPECIALISTS IN CHANGING ECONOMIC SYSTEM OUTLINED

Beijing CAIZHENG [FINANCE] in Chinese No 7, 5 Jul 81 pp 31-32, 12

[Article by Bao Youde [7637 0645 1795], Pei Shian [5952 0013 1344]; "Our Views on the Real Duty of Finance and Tax Specialists in the New Situation"]

[Text] What is the real duty of finance and tax specialists? This is a controversial issue that has not been settled over the past 20 years and more since the start of state-private ownership. With a view to adapting ourselves to the new circumstances, we have held many disscussions since last year on the real duty to be performed by finance and tax specialists in the new circumstances. Some say they should concentrate their energy on "supporting, helping and promoting." Others think their real duty should consist in "inspecting, supervising, and collecting." Still others advocate playing an all-round role and alternating "supporting, helping, and promoting" with "inspecting, supervising and collecting." Below we set forth our fairly concentrated views for discussion with our comrades.

1. What are the new circumstances confronting the financial and taxation work?

Along with further implementation of the 8-character policy centered on readjustment of the national economy, many new problems and new circumstances have arisen in financial and taxation work. As far as the textile and instruments-meters industries covered by the second Shanghai tax sub-bureau are concerned, three main changes have taken place: (1) In the economic system, there have appeared industrial companies, combined industrial-commercial enterprises, jointly operated industrial-argicultural enterprises, jointly operated state-collective enterprises, workshops at state-run plants separated into collectives, and the new economic form of joint Chinese-foreign ventures now being negotiated. (2) Change in the mode of operation. Operation of enterprises has branched out into following lines: processing imported materials, developing compensation trade, setting up sales departments of industrial enterprises, charging technical aids to other enterprises under regional cooperation plans, and expanding floating prices and self-fixed prices among prices of plant products. Instruments and meters enterprises have carried out internal adjustment of prices. (3) Change in the financial system. Five branches of the instruments and meters industries have put into effect the system under which they retain a portion of their profits. Excepting the abovementioned enterprises which account for 85 percent of total number and 90 percent of the financial resources, and which have put into effect the system of profit retention, all the other enterprises have put into effect an enterprise fund system.

All the above changes boil down to one point: gradual expansion of enterprises' power of self-management. The relationship between enterprises which deliver profits to the higher authorities and the state finance which allocate funds is undergoing changes. Although such changes have just begun, tax collectors are already confronted with a contradiction between enterprises and state financial departments fighting for profits. Some enterprises which want to retain more profits and grant more bonuses devise ways and means to put into production cost the expenses that should be defrayed out of their retained profits, and keep sending more and more applications for tax deduction and exemption so as to increase their profits. They invent all kinds of names as pretexts for "squeezing tax and digging up profit." If tax and finance personnel disregard these changed circumstances and cling to the old notion that "the meat is in the pot anyway," it would be difficult for them to bring into the treasury the full amount of profit tax that should be collected. Circumstances are forcing us to ponder seriously over what is the duty-bound job to be done by tax and finance personnel and what should be done by enterprises and the competent departments without its being monopolized by the tax and finance personnel. In this respect, if we face the reality and seriously look back on the past, then we shall find it not difficult to settle the question--what is the duty of tax and finance personnel--that has been discussed for some 20 years.

2. Our understanding about the guiding thought underlying the duty of tax and finance personnel in the new situation.

We think that in the new situation the guiding thought underlying the duty of tax and finance personnel is to achieve the four modernizations. For the present, they should serve the purpose of implementing the readjustment policy in their work, and adhere to the socialist direction, and acquire a political viewpoint, production viewpoint and mass viewpoint. They should strengthen financial supervision, promptly bring taxes on profits into the treasury in full amount, and contribute their part to eliminating financial deficits. In this respect, we must observe the principle that economics determines finance and finance in turn reacts on economics, promote production by performing the inherent function of the socialist finance, and serve production.

As to how to apply the inherent function of finance in promoting production and serving production, we think the following points should be grasped: (1) Financial and taxation policies, decrees, and regulations should be formulated in such a way as to benefit the development of production. (2) Budgets of revenue and expenditure should be worked out in such a way as to benefit the development of production and gradual improvement of people's livelihood. (3) In managing finance and taxation, investigation and research should be conducted, experiences summed up, and the development of production more effectively stimulated. (4) Enterprises should be urged to keep raising their business accounting level. (5) Financial and taxation policies and decrees should be applied in strengthening financial supervision and combating violation of financial discipline. The objective is to insure implementation of financial policies and fulfillment of the financial tasks.

In short, the real duty of finance and tax personnel may be clearly divided into three main points: (1) Determine a starting-point--everything for the four modernizations. (2) Establish a foothold--basing themselves on their real duty and playing their role by performing the inherent function of finance. (3) Determine the end-result--striving for fulfillment and overfulfillment of the revenue targets.

3. Our concrete views on the real duty of tax and finance personnel.

As the saying goes, "The gong beater and the candy pedlar each has his own trade." Not to define clear-cut duty requirements that can be checked and examined is to deny the necessity of social division of labor. We maintain that the job requirements to be met by tax and finance personnel are to do a good job in two spheres: "raising funds" and "reflecting supervision." In other words, they are required to do a good job in "three checks, two management's, and one-collection."

"Three checks" means "inspection, examination and investigation." (1) In accordance with state financial policies and decrees, they should exercise supervision and carry out inspection with regard to enterprises. Such is the duty-bound task of tax and finance personnel, a task no other department can perform on their behalf. They should inspect whether profit tax is fully and promptly paid, how the financial discipline and system are implemented, and how various types of funds are managed and used. (2) Where necessary, they should examine how enterprises deliver profits to the higher authorities and receive allocations from the higher authorities. This is an important link in exercising financial supervision and guarding the financial pass. With enterprise power expanded, more and more things are appearing that require certification, affixing of seals, and declaration of intention by the financial authorities. Moreover, all these things involve the interests of the state, enterprises, and workers. Therefore, inspectors are increasingly required to follow policy and meet work requirements more thoroughly. What should be inspected includes the following: Applications for deduction and examption of tax payments, compensation for losses, write-off of property, compensation-loss allocations and transfers, retention of profits, loans, repayment of loans, as well as enterprise projection of financial costs, and various accounting tables and reports. (3) They should regularly investigate and study the new circumstances and new problems arising from changes in the financial source and from economic growth, so as to keep themselves informed of the circumstances, follow the trends, study measures and reflect developments promptly.

"Two-management's" means, internally, managing taxation and, externally, supervising and urging enterprises to strengthen their financial management. Emphasis should be laid on the former. Internally, management of day-to-day taxation work should be strengthened, normal work order established and perfected and the necessary foundation work overhauled and strengthened to supervise tax payers. In practice, we are of the opinion the day-by-day management of taxation may be concretely divided into ten items: "collection of tax payment, supervision over delivery of profits, projection of income, deduction and exemption of tax payment, return of income to treasury, examination of tables and reports, check-up on finance and taxation, handling of vouchers and receipts, making notes on handbook, asking for instructions and submitting reports." If is necessary to guard against tax arrears, delaying of tax payments, and tax omissions, and to insure prompt fulfillment and overfulfillment of the revenue targets. In short, the real duty of tax and finance personnel must have a relative "limit" in scope and a relative "bottom" in requirement. Everything should follow rule and duties incumbent on each should be clearly defined. In so, the enthusiasm of the vast number of tax and finance personnel can be effectively brought into play and our level of management can really be raised.

COAL INDUSTRY MINISTER DISCUSSES ENERGY POLICY

Beijing MEITAN KEXUE JISHU [COAL SCIENCE AND TECHNOLOGY] in Chinese No 4, Apr 81 pp 4-8

[Abridged version of speech by Gao Yangwon [7759 2254 2429], minister of coal industry and deputy chairman, Standing Committee of the State Energy Sources Commission on 20 September 1980: "On the Issue of China's Energy Policy"; place not specified]

[Text] 1. The Energy Source Problem Is Crucial Issue Concerning Our Country's Four Modernizations and Construction

Energy sources are at once an important material basis for the development of the national economy and an important condition for realizing the four modernizations. This is quite clear if we look at the history of the world's economic development and the actual status of China's national economy. In 1978, the gross consumption of the world's nonrenewable energy sources was equivalent to 8.76 billion tons of coal, of which petroleum and natural gas accounted for 65 percent, coal accounted for 32 percent, hydroelectricity and nuclear power accounted for 3 percent, thus constituting an energy sources structure chiefly composed of oil and gas. In 1950, the world's total energy consumption amounted to 2.7 billion tons of coal equivalent, of which coal accoumted for 61 percent, petroleum and natural gas accounted for 36.6 percent. The 1973 total energy consumption reached 7.8 billion tons of coal equivalent, of which the proportion of coal dropped to 32 percent, while oil and gas rose to 66 percent. Throughout the 1960's, the mean GNP growth of major industrial nations was 4.5 percent, and Japan's mean GNP growth reached 11.9 percent. By utilizing good and cheap petroleum as their primary source of energy, the major capitalist powers succeeded in bringing about modernization within a very short span of time. After 1973, due to the oil crisis, supply shortage and hiking prices, the major industrial powers generally entered a period of low economic growth; the annual growth tapered off to only approximately 2 percent, and Japan's annual growth also dropped to 5 percent. It is now generally believed in the world that the energy problem centered around petroleum is the gravest problem in the world economy of the 1980's. It follows that economic growth is indeed closely tied to the supply and structure of energy sources. The extensive use of a new type of energy in massive quantities is bound to lead to rapid economic growth; conversely, the entire economic growth will slow down or even come to a standstill.

At present, the worldwide energy crisis indicates that the energy sources problem is at a new turning point. In view of the fact that oil resources can no longer ensure long range needs, every country is seeking new sources of energy which can serve as alternatives. It is generally believed that coal and nuclear power electricity are relatively realistic alternative energy sources. There are great reserves of coal which are widely distributed and not so easily monopolized. The nuclear power technique has already been attested and proven economically reasonable; but it is impossible to replace oil or gas with nuclear power within a short span of time. Thus, the only way is to exploit rationally and utilize coal resources.

Our country's energy sources have undergone 30 years of development, and have formed into a pretty solid foundation. In 1979, China's nonrenewable energy sources reached 630 million tons coal equivalent, which included 635 million tons of raw coal, 106 million tons of petroleum, 14.5 billion cubic meters of natural gas, 50 billion watts of hydroelectricity. But there is still a sharp contradiction between supply and need of energy sources, which has already affected that national economic growth. The main reasons are: First, for a long period of time, too much investment has been put into all heavy industries except energy sources industries, not to mention the low priority given to the construction scale of energy sources, thus resulting in an imbalanced development of energy source industries and energy consuming industries. In 1950-78, the annual mean growth rate of energy output was 11.9 percent. During that period of time, the annual growth rate of iron and steel output was 20.1 percent, chemical fertilizers 28.5 percent, caustic soda 17.6 percent, cement 17.2 percent. Second, due to the backward state of management and technique, especially the previous practice of developing small-scale industries which were great consumers of energy but low output producers (small-scale industries accounted for over one-half of all the industries put together), there was serious wasting of energy sources. Third, the serious imbalance of energy sources industries, especially coal and oil, affected the growth rate of energy sources. Fourth, lack of understanding of the seriousness of the rural energy sources problem, plus lack of effective measures. But, in essence, our country's energy problem is not the same as the energy crisis of capitalist countries. Our country has rich energy resources and does not have to depend on importation. Moreover, China's energy industries already have a certain foundation. So as long as we are willing to regard seriously the experiences of history as lessons to draw from, respect science, strictly adhere to objective laws, and make plans properly, it is entirely possible to solve China's energy problems and even try to do a certain amount of exportation by relying on our own resources and the concerted efforts of various sectors and regions.

2. Stress Development and Conservation While Giving Priority to Energy Conservation in the Immediate Future

China's overall policy toward energy sources is to stress development and conservation at the same time, while placing special emphasis on energy conservation in the immediate future. The philosophy behind this is twofold: First, there is not enough time to rely on development in the immediate future. In recent years, due to the country's limited capital resources, large-scale construction of energy sources was out of the question. Moreover, the period of construction for developing energy sources is long; generally, it takes 8-10 years for large-scale coal, electricity and petroleum projects to come into effective use. Thus, in the immediate future, the growth of the national economy must rely mainly on energy conservation instead of placing hopes on development. Second, the utilization ratio of energy is being wasted. For example, in terms of ton steel comparable energy consumption, China consumes 1.6 tons of coal equivalent, and Japan consumes 0.77 tons. In electric power consumption, China used 2.7 tons. Japan used 1.2 tons. If we can attain Japan's level of consumption in these three aspects only, based on 1979's output, it will be possible to save tens of millions of tons of equivalent coal. Of course, this is impossible to achieve without undertaking any great changes. But it does reflect the tremendous potentiality of energy. China's utilization ratio of thermal energy is less than one-third; if the utilization ratio of thermal energy can be raised 1 percent each year, it is equivalent to saving 3 percent of the energy sources, i.e. increasing production by over 10 million tons coal equivalent. Thus, it is of great realistic significance to emphasize giving priority to saving energy in the immediate future. Third, the process of saving energy is actually the process of modernizing production and life. Everything is aimed at modernization, whether it may be changing or improving equipment, or improving production technology, or proper utilization of energy sources. Because of its significance, both the technical reform of the national economy and the great cutback in energy consumption constitute a long-term strategic task and an important step toward the realization of the four modernizations. Fourth, the energy sources industrial sector has the dual task of developing and conserving energy at the same time, but emphasis should be placed on development. Under permissible circumstances, the foremost task of the energy sources industry is to expand the scale of development and accelerate the speed of adjustment and construction progress.

3. Regard Energy Conservation as Central Point in Technical Transformation and Structural Reform

The practice of regarding energy conservation as the central point in the technical transformation and structural reform of the entire national economy is a major and important step toward materializing social modernization. The fundamental point of departure in energy conserviation is to make all-around improvements in the utilization of energy sources, reduce energy consumption per product and per output value, obtain maximum economic results with minimal consumption of energy and thus attain the end of improving both production and the people's livelihood. There are numerous ways of saving energy. To approach the current problems, it is necessary to stress the following measures:

(1) Strengthen Control Over Energy Sources

The strengthening of control has always been an important way of saving energy. First, it is necessary to start from basic work, such as conducting useful general surveys onenergy sources utilization, maintaining effective heat balances, establishing sound control systems to regulate energy consumption quotas, intensifying first-hand recording of energy sources utilization as well as metrological measurements and statistical analyses, etc. These are the necessary conditions for controlling energy sources scientifically. It is also important to make sure that such large energy consuming processes as heat treatment, casting and forging, welding, oxygen production, etc., should be properly controlled under cetralized production management. For instance, by installing 2 heat treatment centers to serve more than 80 factories, Nanjing City can save approximately 1½ energy sources. Great results in energy conservation can be achieved by earnestly popularizing this kind of experience. It is necessary to establish sound management organizations at various levels to control energy sources. Key enterprises which are large energy consumers (over 5 tons coal equivalent of the overall energy consumption) need special energy control setups with technical people specializing in energy sources managment. Ordinary enterprises should have full-time or part-time specialists with expertise in the techniques and management of energy conservation. Besides enhancing energy sources management of the enterprises, the state should also establish related management systems. For instance, it is not only important to give consideration to such needs as energy consuming equipment, production of machines and tools, importation and distribution, but also the conditions of fuel supplying, and strictly adhering to the state's plan.

(2) Carry Out Technical Transformation Step by Step in a Planned Way

As the technical transformation of the national economy is the main direction of approach toward energy conservation in the future, it is imperative to concentrate our efforts in carrying it out. Our country is technically backward; most of the equipment is old, has poor efficiency, and consumes a lot of energy. For example, diesel and gasoline engines manufactured in this country consume 10-20 percent more diesel oil and gasoline than the advanced types of engines made in foreign countries. According to incomplete statistics, some 3.6 million tons of extra diesel oil and gasoline are consumed each year [by Chinese engines]. The efficiencies of China's water pumps and blowers are 10 percent lower than those made in foreign countries; the annual excessive electricity consumption amounts to 10 billion watts. There are now 180,000 boilers throughout the entire country, half of which are either outdated, old or both; their heat efficiency is so low that half of the coal is burnt and one-half is wasted; as compared with advanced type boilers in foreign countries, the amount of excessive coal consumed in a year amounts to over 60 million tons. Moreover, the currently used medium and low voltage generators which can produce 12 million kilowatts of electricity account for 29 percent of all thermal-power generators put together, and consume one-third more coal than large generating units; the excessive amoung of coal in a year is approximately more than 19 million tons. Therefore, these are the problems that should be focused on when carrying out technical transformation.

First, emphasis should be placed on the renewal, modification and remodeling of major energy consuming equipment (e.g. boilers, generating units, combustion engines, cars, tractors, water pumps, blowers, compressors, electric motors, transformers, etc.), it is necessary to establish a uniform energy consumption standard for all kinds of equipment, machines and tools which will be issued and enforced throughout the whole country. The design or manufacture of any equipment, machinery or tool that use more energy than the standard consumption level will not be permitted; those that have already been approved for mass production must be remodeled within a certain period of time. Firm steps must be taken to stop the production of those which fail to comply with the remodeling regulations within the time limit, and thus enforce the remodeling requirements of the equipment. While the remodeling and modification of equipment will entail an enormous expenditure of capital funds; the production of new equipment will also require huge amoungs of capital investment.

In close coordination with the renewal and modification of equipment, there must be development of centralized heating and combined utilization of heat and electricity in urban residential districts or areas where mining enterprises are concentrated and where they constitute stable heat loads. Generally speaking, by combining heat and electricity production, it is possible to enhance thermal efficiency from the current 30 percent level to over 60 percent, especially high temperature, high pressure, retropressure type generating units which produce even more remarkable results in energy conservation. Tehcnology improvement and the use of new types of heat insulating materials are also important technical transformation projects.

It is imperative to strengthen scientific research on energy conservation so as to provide technical transformation with scientific basis and prepare the technical grounds for carrying out energy conservation work.

(3) Reform Economic Structure

To a certain extent, the economic structure of our country should be gradually changed from energy wasting to energy conserving in line with our country's concrete conditions. At present, most of our country's energy sources are used for heavy industries. In 1978, heavy industries accounted for 55 percent of the overall energy consumption, and the light industries accounted for 8 percent; but as far as the national revenue was concerned, the heavy industries accounted for only 29 percent while the light industries earned 18 percent. That year, there was a 4.6 times difference between the energy consumption rates of the two industries computed in terms of per hundred million yuan. It is estimated that the proportion of light industrial output value in the overall industrial output value rose from 41.6 percent of the corresponding period in 1979 to 45.5 percent; as a result, approximately 10 million tons of coal equivalent was saved. Due to the difference of product composition within the various departments of industry, the rate of energy consumption also varies. For example, the iron and steel ratio is 1.07:1 in China, and 0.7:1 in foreign countries; since the energy consumption of iron smelting accounts for 70 percent of the total energy consumption of the iron and steel industry, based on the current production level in our country, it is possible to save approximately 7 million tons of coal equivalent with each oil drop in iron and steel ratio. In veiw of the actual conditions in our country, it is possible to create even greater wealth for the society with the same amount of energy consumption by continuing appropriately to raise the proportion of light industries, and develop more departments of industry that consume less energy, produce greater output values and have concentrated labor.

Medium and small enterprises must undergo gradual technical transformation. Measures such as closing, stopping, merging or shifting must be taken against those large enterprises which contend for raw materials, hunger for fuel power, consume too much energy and can not be transformed at all.

(4) Utilize Energy Sources Properly

By properly utilizing energy sources in accordance with the characteristics of each kind of energy source and the specifications of each type of power consuming equipment, it is possible to make fuller use of the economic benefits of various kinds of energy sources. At present, the comprehensive utilization of energy sources is poor and wasteful; most cities burn coal directly, thus encountering low combustion efficiency and serious pollution problems. The industrial and communication enterprises make very poor use of residual heat; there are quite a few places which merely generate electricity and do not supply heat at all in spite of the fact that they actually have suitable conditions for producing both heat and electricity at the same time. This means that the heat energy is not being fully utilized. Moreover, energy sources are not being properly distributed and utilized; a great number of coal varieties are being supplied to the wrong users. For example, a fly-high loss of 7 percent is incurred as the result of supplying railway locomotives with raw coal instead of lump coal. For best results, medium-size anthracite coal should be used in manufactuing chemical fertilizers; but, at present, since some 80 percent of anthracite does not go through washing or separation, the proportion of small lumps is quite sizeable and the lower size limit rate is high, thus resulting in 25-30 percent consumption increase. What is more, it is extremely uneconomical to use petroleum as fuel. The following measures are proposed to deal with these types of problems.

Substitute coal for oil; compress fuel oil; put stress on compressing various kinds of boiler fuel oils. Power station boilers, industrial boilers and civilian-use boilers which had been originally designed to burn coal but were subsequently converted into oil burners should all be switched back to coal burners in stages and batches within the shortest space of time; industrial boilers and civilian-use boilers which were originally designed to burn oil should likewise be converted into coal burners. Power stations which were originally designed to burn oil should be used as backups or peak regulators, and replaced by newly built coal burning equipment of adequate capacities. As far as production technology, product quality and combustion temperatures are concerned, there are no special requirements for oil burning industrial pit furnaces; but those which can be replaced by coal or coal gas should also be converted into coal burners in stages and batches.

Such inflammable gases as natural gas, liquified petroleum gas (LPG), coking furnace coal gas, etc. should be properly used. First of all, inflammable gases which are discharged into the atmosphere unused should be recovered chiefly for civilian use. As for inflammable gases which are already being utilized, except for those which are used as chemical industrial raw materials, efforts should be made to find out which of these fuels can be replaced and reserved for civilian use.

Proper utilization of coal for urban residents. First, cities with local coal resources should go into coal gasification for civilian use. The industrial cities should take positive steps toward utilizing residual gas, residual heat for civilian use. Places which do not have any such conditions now should stress molded coal processing; vigorously develop washing, separating and processing; improve quality; increase variety; supply according to needs of users and properly utilize coal.

(5) Adopt Economic Policy To Promote Energy Conservation

At present, the price of energy is universally far too low. In January-April 1980, the capital profit rate of major coal enterprises throughout the whole country was relatively low, and incurred fairly extensive losses, thus accounting for only approximately 17.5 percent of the mean profit rate gained by all the industries throughout the whole country. In some areas, the price of electricity is on the low side, thus incurring extensive losses to the whole nation's heat supplying. Therefore, it is imperative to increase the prices of energy sources products at a suitable time so as to stimulate energy conservation. For those enterprises which exceed the state's quota on energy consumption, such measures as levying reasonable surcharges or taxes on excessive energy consumption should be taken into consideration. To those energy consuming organizations which adopt technical measures to conserve energy, the state should extend a certain amoung of preferential treatment and aid in such areas as credit loans, taxation, financial subsidization, material supply, etc. A strict but fair reward and punshiment system should be enforced in the energy conservation program; bonuses should be awarded to organizations and individuals who achieve outstanding results in energy conservation. Economic sanctions should be applied in serious cases of energy wasting. It is necessary to come up with a unified energy reward/punishment system.

(6) Promulgate Energy Conservation Decree

There should be legislation on energy conservation, and it is imperative to enact a series of energy saving decrees that can be strictly enforced; violations must be investigated and dealt with, thus seriously upholding the decrees.

Careful calculation and strict budgeting must be exercised in energy conservation, and comprehensive economic results should be stressed. Self-sufficicency and arduous struggle ought to be encouraged; positive efforts should be made to raise one's own energy conservation funds and use the funds sparingly. Overall consideration should be given to such factors as safety, environmental protection, people's lives, etc., and thus make all around arrangements and avoid giving too much attention to one thing and losing sight of another. It is important to stress chief regions, key enterprises and priority measures. At present, there are 6 major areas which account for over 60 percent of the nationwide total energy consumption, i.e., electric power production, metallurgy, chemical industry, construction material production, petroleum production and railroad. Approximately 50 percent of the total energy consumption comes from various kinds of boilers (including electric power station boilers, industrial boilers, civilian-use boilers and locomotive boilers). As far as the whole nation is concerned, it is especially important for major regions and industries to proceed with energy conservation. Each region and industry must focus on its own particular key point. Generally speaking, energy conservation measures should proceed from easy to hard, and from quick to slow. Planning should be enhanced in energy conservation work, and the key lies in making a long-range energy conservation plan that is scientifically well rounded. Departments and local places must be closely linked, e.g., the overall planning of centralized heating, combining heating with electric power, utilizing residual heat, etc. should be focused mainly on local places. It is necessary to formulate an energy conservation plan that can serve as a guidance, through close collaboration with the Planning Commision, Economic Commission, Construction Commission, Science & Technology Commission, Agricultural Commission, and Machinery Commission.

4. Give Priority to the Development of Coal and Hydropower

Our country is endowed with rich resources of coal and hydroelectricity, and the conditions for development of these resources are fairly good: there are over 64 billion tons of known reserves of coal, and the petroleum reserves hold excellent long-range prospects. As far as the makeup of energy sources is concerned, the proportion of coal will remain at approximately 70 percent from now to the end of the present century. Hydroelectricity is a cheap, clean and renewable source of energy which can be utilized forever. Thus, for a very long period of time from now and into the future, it will be imperative to give first priority to the development of coal and hydroelectricity.

Departing from the actual distribution of China's resources, the development of energy sources centers should be carried out in north China, northeast China, east China and the central south region where coal and thermal power are the primary sources of energy, as well as in the southwestern, northwestern and central south regions where hydroelectricity is the primary source of energy. Positive efforts will be made in oilfield exploration and exploitation, as well as preparations for building nuclear power bases. Vigorous efforts will be made in developing rural energy sources.

Coal: Put emphasis on exploiting Shanxi coal. Shanxi abounds in coal resources. It has a good assortment of high-quality coal. The deposits are shallow and the seams are stable, which makes it possible to develop coal with a low investment plus quick results. There should be a speedup of construction of coal mines in east China, and a build up of thermal power bases in this region. Energetically develop coalfields in the northeast region; carry out unified planning in the three provinces of northeast China and the three eastern leagues of Nei Mongol; build mines, open hearth pits and large thermal power stations in this region. Develop coalfieds in the central and western portions of Henan; construct thermal power bases; expand the electricity power network in central China. Besides the preceding four regions, other regions should likewise develop oilfields selectively, build thermal power stations, and thus meet the local needs for coal and electricity. Shanxi, Guizhou and the western part of Nei Mongol should also develop coalfields as their transportation capacities are improved.

Hydroelectricity: Continue the construction of hydroelectricity base in the upper reaches of the Yellow River in the northwest region; build hydropower bases in the drainage area of Guangxi's Hongshui River, accelerate the development of hydroelectricity in the southwest region where the inexpensive hydropower resources will be fully utilized, and such power-consuming industries as nonferrous and rare-earth metals will be developed. The construction of two hydropower bases in Hunan and Hubei Provinces will be carried on, i.e. the West Hunan Project and the Sichuan-Hubei section of the Changjiang Project; besides the Gezhou Dam and Wuqiang River Hydropower Stations which are currently under construction, hydropower stations will also be set up in suitable locations. In the northeast, east China and north China regions, medium and small-size hydropower stations can be build in suitable locations so as to make the most of hydropower and thermal power which compensate and backup each other.

Petroleum: Strengthen geological exploration for oil. The oil reserves should be increased and expandedat the same time, and new oilfields should be developed.

Nuclear power: Nuclear power is an important source of energy, and should be developed along positive guidelines. At present, the installed capacity of operational nuclear power stations around the world has reached 120 million kilowatts. Practice has proven that nuclear power is safe and dependable. Although it entails a larger investment than thermal power, it can generate electricity at lower costs as compared with thermal power. The development of nuclear power is also an important measure for making adjustments to offset the uneven distribution of energy resources and reducing the burdensome pressure of power transmission. At present, nuclear power can only be developed chiefly in areas which suffer from acute shortages of energy.

Rural energy sources: The development of rural energy sources is an urgent task. First, methane gas should be energetically developed; this constitutes an important direction. Second, plant forests of trees for rural firewood. Departing from the practical situation and in line with local conditions, allocate limited amounts of private plots and private hills to peasant households and encourage them to plant trees in vacant areas to produce locally some of their own fuel. Third, construct small coalpits and small hydropower stations in suitable places. These are the chief sources of energy in the rural area. While small coalpits and small hydropower stations which are not linked to a [power] network ought to be developed energetically, it it equally important to stress overall planning and real results.

Other energy sources: Our country is also endowed with rich resources of geothermal energy, wind energy and tidal-wave energy; and some regions have excellent conditions for utilizing solar energy. To develop such energy sources, scientific research is required, progressing from small to large-scale projects, and conducting experiments at the same time; the results should be gradually popularized in regions with suitable conditions.

In the course of developing energy sources, it is necessary to attach great importance to the coordination between the distribution of industries and construction of power sources. On the one hand, attention should be devoted to solving the energy shortage in economically developed areas in east China and the northeast territory where communication and transportation as well as the construction of electric power networks are to be enhanced. On the other hand, newly constructed energy-consuming enterprises should be placed as close as possible to energy source bases in the future, and energy-short areas should not be allowed to construct large-scale energy consuming enterprises such as ferroalloy, aluminum, calcium carbide, etc. so as to improve the coordination of energy production and marketing in those areas. To develop energy sources, the distribution of industries must be planned as a whole in coordination with communication and transportation, and efforts should be made to strike an overall balance so as to save investments, reduce transportation costs, cut down energy consumption, and thus obtain optimum economic results.

Our country's energy sources industry already has a sure foundation, but the overall technical level is still very low. Thus, it is necessary to step up the development and popular utilization of energy sources, and give full scope to the role of currently available energy science research organizations. Scientific research should focus on finding ways of developing and utilizing conventional energy sources. Our country's energy sources industries should be transformed and equipped with new technology as soon as possible. Moreover, great efforts should be put into scientific research work on new energy sources. For some time to come, coal will remain as the chief constituent of China's energy consumption structure. Environmental pollution control and energy source transportation problems should not be overlooked. On the contrary, environmental protection and energy source transporation should be put on the main agenda of scientific research work. Moreover, a lot of effort should be put into research on coal gasification and liquefaction techniques, and ultimately transform the backward method of burning coal directly. In addition, serious efforts should be put into tapping the potentialities of energy sources industries as well as carrying out innovation, transformation and expansion, and giving full scope to the role of old bases. This way, it is possible to produce quick results with low investments.

In sum, the development and utilization of energy sources involve a very wide area and greatly affect the national economy and the well-being of the people. To reach the goal, we must seek common understanding, keep in step, and act in unison.

ENERGY

STATUS, PROSPECTS OF CHINA'S COAL EXPLORATION TECHNIQUES OUTLINED

Beijing MEITAN KEXUE JISHU [COAL SCIENCE AND TECHNOLOGY] in Chinese No 4, Apr 81 pp 9-11

[Article by Fang Jie [2075 2212], board member of China Coal Society and deputy director of the Geological Bureau of the Ministry of Coal Industry: "The Status and Prospect of Coal Exploration Techniques in China"]

[Text] The foundation of energy sources for realizing our country's four modernizations lies in her rich coal resources. With the rapid growth of the coal industry and the fast improvements in coal production and technology, the requirements in coalfield geological exploration are becoming increasingly harder than ever. New problems, both in depth and scope, are encountered in the various realms of science pertaining to coalfield exploration techniques. To ensure rapid and healthy development of coalfield geology and exploration techniques, it is important to work in line with the actual geological conditions of coalfields in this country, and comply with the requirements of coal industry construction. Moreover, it is necessary to consider the current technical status of our country as well as the development trend of advanced techniques in other parts of the world.

Broadly speaking, the actual geological conditions of China's coalfields are: multiple geological ages of coal formation ranging from the Carboniferous to the Tertiary with one or two coal-bearing rock series in each age; wide coal series distribution, covering approximately one-eighteenth of the whole country's land area; great variation of coal grades and complete range of coal varieties. There are numerous kinds of sedimentary formations and geological structures. Moreover, in general, Paleozoic coalfields have relatively deep deposits with remarkable vertical differences and horizontal variations in the coal series and seams. These natural features also vary greatly between the southern and northern parts of the country; as a result, the specific geological conditions of China's coalfields are somewhat diversified. Thus, in order to attain the desired results in prospecting, it is imperative to adopt various kinds of geological exploration methods and means in line with local conditions.

Through nearly 30 years of geological exploration practice, striking developments have been achieved in all kinds of prospecting techniques, and a fairly large amount of experience has been gained, thus giving rise to a comprehensive prospecting method composed of a multitude of probing techniques that coordinate with one another. For concealed coalfields that have flat topographical features and relatively favorable physical conditions, we have already mastered prospecting methods which combine ground geophysical surveying methods (i.e. gravimetric and magnotometric, electrical, seismic) with drilling and well logging; for exposed coalfields, a fairly good amount of experience has been gained in applying prospecting methods which rely on airborne topographic surveys and aerial geological mapping for guidance, and combine mountain stripping projects with exploration logging.

Our technical forces, survey teams, and capacity to manufacture equipment, drills, and geophysical instruments are quite adequate to support several hundred geological prospecting projects each year. In view of our country's coal mine production and construction needs, as well as the technical development trend in foreign countries, it is evident that we still need continuously to improve the accuracy of geological work, expand its scope of surveying work, and enhance the ability to solve practical problems. Various kinds of exploration techniques are being developed toward high quality, versatility, quantitative, microscopic and macroscopic, automatic [recording], series and digital techniques.

Following are some of the author's views on various subjects related to geological work, drilling, geophysics and the procedures of exploration work.

1. The ultimate goal of every operation in the geological exploration sector is to probe for mineral resources meeting certain quantity and quality specifications; and a geological report is the concentrated expression of the results of this particular kind of work. Thus, the quality of a geological report reflects the overall quality of the results achieved in a geological survey through various kinds of operations, disciplines and methods.

As proven by 3 decades of practical experiences, it is imperative to focus on high quality geological reports based on technically and economically sound exploration methods. To attain this end, first, it is necessary to do basic work including gathering and recording all kinds of firsthand information and make corresponding measurements and lab tests so as to obtain more scientific data which will enable comprehensive evaluation of the mineral production and thus bring our knowledge even closer to the objective facts. Second, process the various kinds of geological information and primary analytic data, and conduct comprehensive research on laws governing the natural occurrence of minerals, and how various geological factors contribute to their formation.

In recent years, many geological teams working in the comprehensive study exploration region have achieved encouraging results in such areas in the paleogeography of rock facies in the coal-forming period, research on structural features, and how they affect coal-bearing basins and rich coal zones, and probing into the variation patterns of coal metamorphism.

To improve the quality of geological work; in recent years, we have formulated and enforced certain standards for coal resources exploration as well as all kinds of rules and regulations on relevant techniques. Obviously, as the productive forces develop toward higher levels and are attested to in practice, after a certain period of time it will become necessary to make essential changes and additions in the standards and regulations.

Topographic surveys, engineering surveys, geological mapping, sampling and lab tests, measurements and tests, etc. all comprise the foundation of geological exploration work. From the viewpoint of development, both macro and micro operations are bound to develop in the direction of automatic [recording] and quantitative techniques. The application of mathematical geology and mathematical statistics in solving practical problems in various disciplines will become increasingly extensive. The application of aerial photography in surveying and geological mapping has progressed through a period of development to the present state-of-the-art which enables topographic charts with scales up to 1/10,000, 1/5,000-1/2,000 and corresponding geological mapping tasks to be accomplished by combining aerial pictures with field investigations. The application of satellite remote-sensing data in coalfield geological exploration is merely a beginning, and intensive efforts are being made to study and try out this new technology. The practice of relying on observation by the naked eye and qualitative descriptions in the identification and testing of coal and mineral ores is no longer suitable for the development of modern geological science, and it is necessary to move toward microscopic, quantitative and automatic recording, and gradually expand their application area. More testing methods and evaluation indices are needed for testing coal in laboratories; this will enable measurement and test work to become microscopic, integrated and versatile. Coal petrology is now further removed from the classroom and it has taken a new step forward in such application fields as the determination of coal metamorphism, separability, sedimentary environment, as well as coal composition and comparison.

For some time in the past, hydrogeology and engineering geology developed at a relatively slow pace. But through enrichment and development over the past 5-6 years, it is now possible to solve fairly complicated hydrogeological and engineering geological problems encountered in coal resources exploration. In the area of technical equipment, blowers are being gradually replaced by the introduction of deep well water pumps and submersible electric powered pumps. Moreover, we have also successfully developed flowrate loggers. Through practice, we have devised an engineering geological surveying system which can be used to determine the hard rock contents of large-scale open-pit mines. In the future, continuous efforts will be made to popularize the application of theories on unsteady flows and numerical values as well as computing technology which were developed in recent years. Efforts will also be made to gradually find means of exploring karst water at the bottom of coal formations and solving key technical problems such as water burst prediction, open-pit side-slope exploration, developing new and special instruments and equipment, etc. We will develop an effective system for exploring all kinds of coalbed hydrogeology and engineering geology, and come up with corresponding basic theories and new techniques.

With the ever expanding application of electronic computing technology, the quality and speed of work are bound to undergo fundamental changes.

2. At present, drilling and geophysical surveying are still the principal technical means of coalfield exploration both in China and other countries. In our country, exploratory drilling is even more important. As compared with other countries in the world which are involved in coalfield exploration, China is among those which operate the largest number of drills. In the 1960's, our drilling technique was not so far behind the level of advanced countries. Up to now, we still have a

fairly strong manufacturing capacity. At present, the key to improving drilling technique lies in our ability to use the equipment and techniques currently available in the country in an effort to improve drilling techniques and boring technology, strengthen basic work with emphasis on high quality and efficiency.

Percussion drills constitute the main body of drilling equipment. Our country began to develop percussion drills in ancient times, and we have now developed the fourth generation, i.e., hydraulic rotary power feed drills. Second generation drills (drive boring without vertical shaft) and third generation drills are mostly used in China's coalfield geological exploration system. Our country is currently developing and testing fourth generation drills which we have designed and manufactured by ourselves.

Through many years of practice, we have accumulated a great deal of effective technical experiences in coalfield drilling, including drive-shaft drilling technique, deep-bore hole technique, coreless boring, small diameter boring technique, alloy drill bit, pipe threader, and movable operating platform, as well as the recently produced truck-mounted cranes, artificial diamond bits, etc.

With the growth of modern probe drilling, further and continuous efforts are still required in carrying out research and development projects in such areas as long-life drill bits, cord-coring technique, hole-bottom drag bit replacement, and expansion drill bits, etc., as well as establishing series standards for drilling equipment and pipes. At present, there is an urgent demand for stepping up basic work in drilling technology, e.g. tests on the drillability of rocks commonly found in various kinds of coalfields in our country, and establishing unified indices; development and series standardization of drill bits for all kinds of rock formations; transformation of coring equipment and instruments for determing layers which are related to the rate of rock coal coring; improvements in drilling equipment and loading/transportation machinery....

The innovative development of probe drilling equipment and technology directly affects the speed and quality of exploration work. But how is it possible to develop a drilling techniques that is fairly adaptable and yet materialize series standardization at the same time in such a country as ours which has a multitude of geological teams, and a great variety of topographical and geological features? This is indeed a problem that merits in-depth probing.

3. The types of geophysical methods which are commonly employed in China's coalfield exploration are: logging, ground seismic prospecting, ground electrical surveying, gravimetric surveying and magnetic prospecting. Logging is used most extensively.

Since the beginning of the 1970's, European countries and the United States have begun to apply advance petroleum geophysical prospecting techniques in coalfield exploration. Broadly looking into the current international level, high resolution seismic techniques, channel wave seismic techniques, and digital logging techniques are the three cardinal indices for developing the application of geophysical techniques in coalfield exploration. Compared with the world's countries with more advance levels, China's coalfield geophysical exploration techniques are relatively inferior. As coalfield exploration develops toward the deep reaches of concealed areas, and as the mechanization of coal mining excavation improves, it will become necessary to solve the numerous geological problems which confront coalfield geophysical exploration.

Coalfield Logging Technology: Our country began coalfield logging in 1954. As coalfield methods and technical equipment are constantly being perfected, striking improvements have been made in the capacity and precision of well logging in solving geological problems. Now it has become an indispensable method in coalfield exploration. Moreover, it has already begun to gradually develop from qualitative interpretation to quantitative interpretation.

Since the 1960's, full automatic photodot recorders have come into extensive use. Other successful developments include: 4-parameter simultaneous loggers composed of apparent resistivity, spontaneous potential, gamma and gamma-gamma combinations, and the extensive application of complete bore hole interpretation, graphic correlation, and hydrological logging techniques, which have thus helped to improve our ability to determine the stratigraphic division and thickness of coal beds, determine the structure of coal seams, and slove problems related to coal strata correlation and hydrogeology. In the 1970's, with the progress made in research and development work on new methods and new instruments, new developments are achieved in the comprehensive study of log data and graph correlation. The introduction of digital electrostratography, supersonic imaging, digital tape recorder and flowlog/induction caliper combination instrument has helped to fill up the gap in our country's logging tecnique in recent years. There have also been some developments in the methods and contents of log data interpretation, and useful research has been conducted on the determination and correlation of rock and coal horizons and stratifications, thicknesses and structures, as well as fault points, sedimentary phases, cyclic structures, rock pressive strength, and the determination of ash contents in coal, etc.

Looking into the logging techniques of tomorrow, it will be necessary to research and develop further new methods and new instruments, such as acoustic logging and neutron logging, in order to solve more geological problems. All kinds of logging instruments will be subjected to quantitative calibration, and instrument graduation will be enhanced. To gradually realize the modernization of logging technology, efforts should be made to study and employ digital logging techniques.

Coalfield seismic survey techniques: Our country has been using this technique for 27 yeras now. In the beginning, photodot recorders were frequently used with the refractory survey method for marking out the basic rock morphology and the scope of coal series distributed beneath the overlying strata; now, the analog tape recorder is used extensively with the common reflection point method for multiple coverage operations. In regions with relatively favorable ground and physical conditions, it is possible to determine the thickness of overlying strata and the relief of the basements, and survey the geological structures--including faults with gaps measuring over 30 meters. The ground seismic method has become the chief means of coalfield geological surveying. Moreover, seismic survey technology is also developing toward digital technique, and, in recent years, the first-ever coalfield exploration digital seismic equipment has been developed. To improve the precision of seismic surveying, it will be necessary to develop new seismic techniques, such as ground high resolution seismics, inter-bore seismics and common-layer (channel-wave) seismics.

Coalfield electric logging prospecting technique: The electrical surveying method was first put to application in 1955 when it was primarily used for probing concealed coalfields. Subsequently, other methods were graudally introduced, e.g., electrical profiling, spontaneous potential field method, induced polarization method, and charging method, etc. By the 1970's, our country could design and develop its own bore hole radio perspective viewer, frequency depth prober. Now, it is already possible to use the electrical surveying method to map out the boundaries of concealed structures, trace the outcrops of coal seams in shallow overlying areas, probe the depth and distribution of coal series under overlying strata, and determine old pits and burning areas.

Digital technology is the trend of development in electrical surveying. Research and development projects on digital frequency depth probers are currently underway. Meanwhile, it is also necessary to expand the application range of electrical surveying, especially in general surveys for coal, regional prospecting, and coal production/exploration stages involving mining geology and engineering geology.

Gravimetric method and magnetometric surveying: Used primarily for surveying regional tectonic framework and igneous rock distribution; high precision gravimetric/magnetometric surveying can also be used for determining the scope of natural zones in coal seams and for studying small faults. In the south, some coalfields have achieved certain results in utilizing gravimetric detail survey data for determining the overlying thickness of red layers.

The application of any geophysical technique is limited by certain conditions. This is especially true in ground geophysical exploration which is often affected by such factors as ground surface conditions, excitation conditions in shallow layers, and physical conditions in deep strata. Thus, it is important to choose the appropriate method in a given location according to local conditions.

4. In order to speed up the construction of the coal industry and enable the country to achieve even greater results from its capital construction investments and currently available tecniques and methods, it is necessary to make improvements in the procedures and methods currently employed in the basic construction of China's coal industry. Is it not conceivable to divide coalfield geological exploration work into two major stages--resource surveying and mine surveying?

INDUSTRY

MEASURES TO DEVELOP SHANXI CONSUMER GOODS INDUSTRY EXAMINED

Taiyuan SHANXI RIBAO in Chinese 23 Jun 81 p 1

[Article by Zhang Baoshan [1728 1405 1472], Yang Guangyu [2799 0342 5940], and Song Liangtu [1345 5328 0956]: "Ways To Develop Daily Consumer Goods Industry in Shanxi"]

[Text] Recently, leading comrades of the central authorities have given instructions on the development of the national economy in our province, laying particular stress on the importance of developing consumer goods production and increasing the annual growth rate of consumer goods production by every conceivable means. As borne out by practice over the psst 30 years, these instructions are fully in line with the objective requirements of industrial readjustment in our province and are directed against the long-time bad practice of the unbalanced development of industries over the past decades. The foundation for the production of daily consumer goods is quite weak and production development is quite slow in our province. Therefore, this link must be firmly grasped so that a coordinated growth of the national economy can be insured in our province.

Broadly speaking, daily consumer goods include all the kinds of material consumption necessary for the masses of the people to make a living. Like production consumption, it must be constantly made up; moreover, from the Marxist standpoint production consumption is conditioned in the final analysis by the consumption of daily necessities. But it is precisely this point that for various reasons was grossly overlooked for a long time in the past. Since the founding of the republic, the annual progressive rate of growth in purchasing power has reached 11.8 percent in our province, the highest nationwide. Last year's commodity buying power reached 5.6 billion yuan, and the per capita purchasing power was 18 yuan higher than the national average. However, commodities available for supply amounted to only 5 billion yuan, including industrial consumer goods, 50 percent of which were brought in from other localities. This being the case, vigorous development of daily consumer goods production in our province is an urgent necessity that must be met in order to satisfy the ever-growing material and cultural needs of both urban and rural people in accordance with the basic economic laws of socialism.

We are now carrying out industrial readjustment primarily to bring into line the economic proportions that have been thrown out of balance and change the irrational economic structure into a rational one.

Shanxi is an important base area of our country and its heavy industrial structure has historical reasons, but practice has proven that the existing industrial structure is unfavorable both to all-round stimulation of the provincial industry and to the development and construction of an energy base itself. Over the past 30 years since the founding of the republic, the proportion of light industry in the gross provincial output has dropped to 28 percent from 48 percent recorded in the rehabilitation period, while that of heavy industry has risen from 5 percent to 72 percent. The per capita output of light industry in the province is now only 139 yuan in value. Initial readjustment was carried out last year when the principle of "six preferences" was maintained in the development of the light industry, and the production of 37 items of major consumer goods including bicycles and sewing machines was undertaken, with the result that the growth rate of light industry rose to 31.29 percent. The products and output increased, the variety of designs and colors increased, the quality improved, and the pace ahead was speeded up. This shows that to continue to grasp the link of developing daily consumer goods production and to gradually push the metallurgical, machine-making and chemical industries to serve the light and textile industries will make the economic readjustment go forward in a rational direction.

The advantages of developing the light and textile industries--less investment, quick returns, source of increased revenues and profits--have always been generally recognized. On the other hand, viewed from the reality of our province, the production of more good quality and inexpensive consumer goods will withdraw money from circulation, cut down the issue balance, and effectively bring the ever-increasing circulation of money and currency outflow under control. The amount of money in circulation on the provincial market is constantly higher than the quantity of available commodities, and currency outflow to Beijing, Tianjin, Shanghai and other provinces and municipalities accounts for 77 percent of the absolute issue balance. In normal circumstances, such a huge amount of outflow should be a factor stimulating the development of consumer goods. But for a long time it has been a millstone around our neck, affecting tax revenues and profits and the capacity for enlarging reproduction. The positive measure for resolving this contradiction is still to rely on the development of consumer goods production in our province.

In the course of industrial readjustment over the past 2 years, a number of districts and departments have gained many good experiences and found many good methods to develop consumer goods production. These experiences and methods are worthy of being summed up and popularized by us.

First, the road to specialized cooperation and combination centered on famous-brand and major products. We may begin with famous-brand products and organize existing industrial structure and according to specialization planning. The combination may assume various forms. In substance, the combined enterprises may concentrate on any of the following lines: developing products, carrying on technological and technical cooperation, processing raw materials through cooperation, raising funds, operating and circulating, and providing services. In extent, the combination may be close-knit or loosely woven and may be overall, single-phased, or overlapping. Or else, on the principle of specialized cooperation and economic rationality, enterprises may be readjusted and formed into specialized companies of various types; or within a municipality or an area, several plants producing similar products and cooperating closely with one another may be combined into a general plant with one major plant as the backbone or formed into "one continuous line" of production. In light of the conditions of our province, it is desirable to start with combining enterprises within the light and textile industries that are in the same localities, such as the Changzhi Bicycle Industrial Company and the Changzhi Sewing Machine Industrial Company. This is conducive to stable and dependable relations in a combination, insuring production coordination and balanced production, and increasing the rate of accessories production. It also benefits the elaborate division of labor among various enterprises and promotes raising the level of specialization. Later, we should organize combinations cutting across trades, departments, areas, provinces and municipalities and combinations between industry and agriculture and between town and country. For the present, we should mainly undertake the combination and cooperation with regard to transistor radios, TV sets, clocks and watches, washing machines and industrial sewing machines and, on the basis of studying the advanced experiences of Shanghai and other fraternal provinces and municipalities, go a step further and make the technical cooperation a success between the Changzhi Sewing Machine Plant and Shanghai Sewing Machine Plant No 1, between the Changzhi Bicycle Plant and Shanghai Bicycle Plant No 1, between the Shanxi Radio Plant and Shanghai Radio Plant No 4, between the Yangquan Watch Plant and the Shanghai Watch Plant, between the Shanxi Textile Mill and Shanghai state-operated cotton mills Nos 13 and No 15, between the Yanbei Porcelain Plant and the Tangshan Porcelain Plant, and between the Taiyuan Porcelain Plant and the Jingdechen Porcelain Plant in Jiangxi, in order to improve product quality, increase the variety of colors and designs, expand production capacity and more quickly increase the production of consumer goods urgently needed by people.

Second, the road to tapping the latent power and carrying out innovations and transformations centered on expansion of production capacity. This is the way to speed up development of the light and textile industries and to increase the capacity for producing daily consumer goods. The existing light industry and textile industry enterprises in Shanxi have great potential. The latent power of old enterprises has not been brought into full play, as manifested in the following: 1) Most of the equipment in our light and textile industries was produced in the fifties, and a small part was produced in the thirties and forties. In order to modernize the variety and quality of products step by step to meet market demands at home and abroad, it is imperative to renew and remake this old equipment systematically according to plan. Some equipment is comparatively recent, but due to the low technical level and the poor foundation of management, has not reached its designed capacity even to this day, leaving still more latent power to be tapped. 2) Over the past 30 years and more, the enterprises in our light and textile industries have built up "technical resources"--large numbers of college graduates trained in practical work, self-taught technicians, and veteran workers rich in practical experience. These "technical resources" have not been fully tapped. 3) Manifested in economic results, labor productivity is low, profits are small, and utilization of funds is poor. Take labor productivity, for instance: the material and technical equipment in our light and textile industries is not compatible with labor productivity. The labor productivity of personnel in Shanxi's light industry was 11,750 yuan in 1979, the 24th place nationwide and 68.5 percent of the national average. If labor productivity can reach the national average, the output value can be increased by 1 billion yuan a year. If it can reach the Shanghai level, the output value can be increased by 4 billion yuan. The labor productivity of personnel in Shanxi's textile industry was 10,835 yuan, the 19th place nationwide and 58.6 percent of the national average. If it can reach the national average, output value can be increased by 1.73 billion yuan. This shows that a great deal can still be accomplished by tapping the latent power and carrying out innovations and transformation in our light and textile industries.

Considering the fact that the financial resources of the state are still quite strained, it is not possible to spend a lot of money to tap the latent power and carry out innovations and transformations in the light and textile industries. Therefore, we must act in accordance with our capabilities, proceed in an orderly way and step by step, pay great attention to economic results, and use our limited financial and material resources to fill the gaps in production of products that are in short supply on the market, to upgrade and change products, to improve product quality and increase the variety of colors and designs, and to conserve energy and cut down the consumption of materials. For example, the funds for tapping the latent power and carrying out innovations and transformations in the textile system should be used mainly for the purpose of renewing and remaking the equipment of existing knitted goods plants and filling the gaps, for the purpose of adding combing equipment, wide looms for making medium-length and long fabrics to meet market demand, and wide cloth and color fabrics. If funds are used for these "essential" purposes, then a capacity for producing 5 million meters of medium-length and long fiber cloth can be established after transformation, and 11 small yarn-dyed fabrics factories can be developed in the direction of producing light weight and thin fabrics. For another instance, if the first light industry succeeds in implementing certain technical measures centered on improving the quality of famous-brand products and products that are in short supply and on the expansion of production capacity, the Taiyuan and Datong breweries and the local famous-brand wine projects can round off the work and establish a capacity for producing 500 tons of aluminum foil paper for cigarette factories and 1,200 tons of baby foods, solid haw drinks, and canned foods. If the projects financed with the funds arranged to tap the latent power and carry out innovations and transformation in the light and textile industries are properly managed and used, they will form a capacity which is expected to increase output value by 370 million yuan, profits by 34 million yuan, and taxes by 29.5 million yuan. The production capacity can be expanded and economic results improved.

Third, basing ourselves on local resources and establishing a stable raw materials system and a raw materials base. In developing consumer goods production we should first rely on diversification of agriculture for raw and processed materials and second on heavy industry for providing raw materials products. In addition, when necessary we may bring in some materials that are in short supply. In this spirit we should base ourselves on local resources and construct a dependable raw materials base. In fact, if 900,000 mu of cultivated land is set aside in Shanxi to develop sugar-bearing crops and tobacco leaves, we can produce 50,000 tons of sugar and 400,000 cases of cigarettes without adversely affecting grain production, while at the same time we can increase the peasants' income and state revenues. The metallurgical and chemical industries, too, should make efforts to provide the light industry with quantities of good-quality raw and processed materials that are up to standard, while speeding up their steps of readjustment. For the present, they should meet as quickly as possible the urgent demand for strip steel and sheet metal necessary for the light industry, and the chemical department should meet the urgent demand for soda ash and caustic soda. This is necessary not only for the development of consumer goods production but also for finding a way out for these departments. It should be borne in mind that the consumer goods industry is itself a processing industry which cannot produce without materials. With the demand for daily consumer goods constantly rising, the demand of the light industry for raw and processed materials from heavy industry will be showing an upswing. How to act as a go-between, guide the water to the channel and keep establishing and perfecting the raw and processed materials systems between consumer goods production and other departments is a problem that needs to be throughly studied, considered and solved further by all those who are interested in the development of consumer goods production.

Fourth, strengthening leadership and encouraging all trades to aid consumer goods production. First, leadership in industrial adjustment should be strengthened. Over the years, whenever a contradiction has arisen between heavy industry and light industry regarding funds, power, fuels, and materials, it was always heavy industry that was "insured" and the light industry that was "pushed aside" whatever the issue. Take capital investment, for example. Viewed from the standpoint of industrial investment over the past years since liberation, light industry has accounted for only 7 percent of the total industrial investment. This has brought about a situation in which the heavy industry is getting ever "heavier" and the light industry ever "lighter," and has brought about a severe imbalance in the proportionate relations between the two major categories of social reproduction. In the process of readjustment a task of top priority is to bring heavy industry from the path of "a closed circle" to the orbit of serving agriculture and light industry. At the same time, the product structure and organizational structure of the light and textile industries themselves should be properly readjusted, and both production of high-grade products that get more income and production of popular products urgently needed by the people should be firmly undertaken.

In order to strengthen leadership over the production of daily consumer goods, it is also necessary to organize coordination between the various branches of the national economy and to encourage all trades to aid the development of daily consumer goods production. Leading bodies at all levels should effectively grasp the change of product structure and adjustment of the direction of service in heavy industry, particularly in the metallurgical and chemical industries, and should strive to provide quantities of good-quality and raw and processed materials that are up to standard for developing consumer goods production. The force of heavy industry and, in particular, the equipment and processing capacity of the machine-building industry should be reorganized according to plan, and everything possible should be done to provide more and better technical equipment for the development of consumer goods production and to help the consumer goods industry carry out a technical transformation and raise its levels of production, technology and management. As in Shanghai and Tianjin the vacant plant buildings and idle equipment in heavy industry should be readjusted and the light and textile industries should be helped to stretch the goods in short supply, fill the gaps and develop famous-brand products. At the same time, the enterprises in the munitions industry should be organized to launch an army-people program to trial-manufacture and produce consumer goods. On the principle of "six preferences" for the light and textile industries, all departments concerned should arrange the necessary funds, supply goods, link production to marketing, open the channels between supply and demand, conduct market survey, and strengthen market forecast. The objective is to insure that the quantity of daily consumer goods maintained in society does not reach a saturation point. In addition, from the Marxist point of view that social production presupposes three essential factors--means of labor, objects of labor, and laborers--the means of labor necessary for the light and textile industries are conditioned by heavy industry, the objects of labor necessary are to be supplied by industry and agriculture, and the laborers necessary are to be provided and trained by the labor department and departments of science, technology and education. This shows that only when all branches of the national economy switch to the orbit of aiding consumer goods production and create conditions for the light and textile industries can the pace of producing daily consumer goods be speeded up.

Speeding up the development of consumer goods production is a glorious and pressing task confronting us. There are many difficulties, but there are more numerous favorable conditions. If we firmly implement the line and policies laid down at the Third Plenum, exert great efforts, show great proficiency, correctly handle the internal connections in the production of daily consumer goods, correctly handle the external horizontal and vertical connections, concentrate forces, and grasp the Taiyuan, Datong, Yangquan, and Changzhi municipalities which account for 60 percent of the total output of the light industry, then production of daily consumer goods will certainly achieve rapid and good progress and development in the course of readjustment.

DECENTRALIZATION OF EXPORT TRADE URGED

Guangzhou GUANGZHOU RIBAO in Chinese 28 Jun 81 p 4

[Editorial by Xie Wei [6200 1919] entitled: "Export Business Should Be Decentralized"]

[Text] Last Sunday I dropped in on a friend who works in a provincial foreign trade corporation and just as I started talking about some provincial corporations which as yet are unwilling to decentralize export business down to local and municipal corporations, he, in one breath and with a heavy heart, set forth numerous "reasons" why decentralization couldn't be.

To sum it all up, he had three "reasons": A lot of commodities require a so-called coordinated transaction, and it is necessary to comply with the principles of unified pricing, market arrangements, and customer usage. If more than one entity transacts the business then "unification" would not be easy; there are a lot of new personnel in municipal corporations who have little experience and do not take enough care; and if local and municipal corporations demand to transact their own exports, the provincial corporations will have no commodities to export. Wouldn't that be "closing down for good?"

Parden me for impolitely stating that this is very near being a "Chicken Little." In the final analysis I fear that it's that there is not accurate understanding for the following three "relationships".

The first relationship is one which gives play to local enthusiasm with centralized unity. The policies of foreign trade naturally require centralization. The goals are expansion of the market and sales at a good price. Also this one point must be made, the problems discovered when local and municipal foreign trade corporations directly conclude export transactions and have an intense grasp of foreign market demand are immediately solved through local party leadership, affirming the benefit of this method over handling through provincial corporations. Not only is this the case, but it can also give full play to the local and municipal enthusiasm in the areas of storage, transportation, banking, etc. It also omits the allocation link from municipality to province. The speed of exports and exchange settlement is far faster than when done by the provincial corporations themselves. Furthermore, foreign transactions emphasize concentrated centralization pointing out the policy level centralization, that being the "three centralizations" of price, market arrangement, and customer application. Only after provincial corporations are decentralized can the control methods of the "three centralizations" be perfected, strengthening supervision of the local and municipal corporations. This will not only implement policy on centralization but can also make business better and more lively.

The second relationship is one between those unfamiliar with the business and the skilled. The unfamiliar and skilled of the so-called cadre operations can only be transformed through practice. Recall that in the early 1950's the provincial foreign trade corporations were just established and the majority of cadre were transferred in from business departments and units. Through more than 20 years of practice, many of them have become "foreign trade specialists." There are a lot of cadre in present local and municipal corporations who have worked in foreign trade for more than 10 years, not to mention that there is also a continuous influx of many specialists who have graduated from foreign trade schools. For this reason, only if the provincial corporations provide more guidance can they take up this secondary responsibility.

The third is the relationship between the upper level corporation and the basic level corporation. There should be a difference in the duties of provincial foreign trade corporations and the local and municipal basic level corporations. In addition to managing its own portion of specific business, the provincial corporation should place its primary emphasis on policy guidance and management of the local and municipal basic level corporations and not mainly on the handling of specific business matters like the basic level corporations, otherwise, they will be unable to play the leading role of a key department. The key departments of foreign businesses do extremely detailed research of the economic trends, international finance, and product demand of every country. Thus, they are able to insure the expansion of foreign sales and overwhelm their competition. As for internal administration, continuous attention is given to improving management, raising work efficiency, and to increasing economic results, so as to guide the affairs of the business. If our provincial foreign trade corporations were also able to decentralize the majority of export business down to local and municipal corporate management and to increase their research and guidance role, then their duties would be extremely strenuous and there would be no talk of "closing down for good."

In March of this year, the provincial foreign economic conference made a decision to give priority to developing the foreign trade of the city of Guangzhou and asked provincial level corporations one after another to pass the conclusion of export business down to municipal corporations. This was an energetic measure to quicken the expansion of the foreign trade of our province. However, only if it is unanimously implemented. I hope those heavy-hearted comrades will liberalize their thoughts, broaden their vision, and make a contribution to the great expansion of the foreign trade of our province.

CONTINUALLY RISING LIVING STANDARDS FOR WORKERS REPORTED

Shanghai WENHUI BAO in Chinese 2 Jul 81 p 1

[Communique from the Beijing bureau by Qiao Quan [0829 6692]: "Constantly Rising Living Standards for Workers and Staff Following the Founding of the People's Republic"]

[Text] Data recently supplied by the Institute of Economic Research of the China Academy of Social Sciences shows that in the 33 years since the founding of the People's Republic and along with the development of production, the living standards of the vast workers and staff of our nation have continually increased.

This report by the Institute of Economic Research, entitled: "Seeing the Superiority of the Socialist System Through the Continually Improving and Rising Living Standards of our Workers and Staff", points out that from the beginning of the People's Republic to the end of the first Five-Year Plan, the productive forces of our society developed rapidly and the people's living standards advanced apace. Later, our work developed some deviation, particularly during the 10 years of internal disorder, exhibiting vast political upheaval, seriously harming the productive forces of society, and hindering the improvement of the people's lives. However, in sum, following the expansion of production, the lives of our workers and staff still showed distinct improvement. According to 1980 studies of 86,955 households of workers in Beijing, Shanghai, Tianjin, Wuhan, and 44 other cities, the monthly cash income is 42.8 yuan, calculated on the average family population. This is 1.1 times greater than 1964. After discounting for inflation factors, the actual living expense income still increased 68.8 percent, a yearly average increase of approximately 3.3 percent.

It can also be seen from this data that in over 80 thousand worker households, the proportion of high income households rose to a great extent and the proportion of low income households dropped to a great extent. Of these, households with monthly incomes of 35 to 50 yuan, when calculated on average family population, increased from 5.8 percent in 1964 to 36.8 percent; and households with incomes below 15 yuan dropped from 32.8 percent to 1 percent. What a gratifying change!

The primary reason for the clear increase in living expense income for worker households was the clear increase in the number of employed persons in worker families. In 1964, each worker household averaged 1.6 persons employed and in 1980 this figure increased to 2.35 persons. In addition, in recent years, due to resolute implementation of planned parenthood, the average population per household declined. Employment grew, family size decreased and the burden decreased. Furthermore, in recent years, workers' wages have also improved and there have been increased bonuses and some allowances with the average income of worker families exhibiting a corresponding increase.

From the results of this survey it can be seen that the average living expenses and the structure of those expenses for workers have both shown a fairly obvious change. In a comparison between 1964 and 1980, the total food expenses for worker families increased 63.3 percent. However, the proportion showed a relative decrease of 8.8 percent. The proportion of income in fuel expense also showed a relative decrease of 2.5 percent. The expenditures for clothes, daily necessities and entertainment actually increase 9 times. This is forceful evidence of the improvement in the worker's living standards.

The number of people possessing medium high grade durable consumer goods amongst the workers also increased steadily. At the end of 1980, 127 bicycles, 66 sewing machines, 85 radios, 32 television sets, 22 electric fans and 5.4 record players were owned by 100 average worker households.

The above survey data also did not include public medical services, rent allowances, in kind awards, and other non-cash income. The system of free medical services, financial assistance, and pensions for our workers can be called the ultimate social insurance. It allows the workers to have no fears of birth, old age, sickness, or death.

STATE SUBSIDIES ON CONSUMER SPENDING DESCRIBED

Beijing CAIZHENG [FINANCE] in Chinese No 7, 5 Jul 81 pp 27-28

[Article by Beijing Municipal Planning Committee: "How Does the State Subsidize Consumer Spending?"]

[Text] The wage system in force in our country is a low wage system. In recent years the party and government have taken a series of measures like adjustment of wages, granting nonstaple food subsidies, and restoration of the bonus system to raise the level of workers' wages. This is obvious to all. But, in addition to income items that are in the nature of wages (including bonuses and allowances), the state spends a lot of funds to subsidize the people on consumer spending. This is often not so apparent to many of our comrades. With a view to studying comprehensively the way the people have increased consumer spending and improved their living standard, we have recently collected some data on how the state subsidized consumer spending for the people of Beijing during 1980. We have made a preliminary analysis of this data. Our findings are roughly as follows:

It is preliminarily calculated that the number of employed in the municipality had a per capita wage income of 880 yuan in 1980, averaging 560 yuan per capita for the total population of the municipality. According to incomplete calculation, the expenses defrayed by the state through various channels to subsidize consumer spending by the people averaged 400 yuan for each of the urban population. Put together these items gave each one of the urban residents an actual income of 960 yuan. At present, the number of employed and the number of retirees (with fixed income) in our municipality account for 70 percent of the urban population (in capitalist countries in general, the number of employed account for about 30 percent of the urban population), and the living standard of the people has much improved.

There are four different funds used by the state to subsidize the people's consumer spending:

1. Allowance for the difference between purchasing and selling prices of basic necessities of life. Policy-related subsidies for grain, edible oil, meat, eggs and vegetables and for coal for civil use totalled 400.67 million yuan, averaging 78.6 yuan per capita of the urban residents. This does not include the reasonable profits on handling these commodities. Actual benefits enjoyed by the urban residents would be much greater if these profits were taken into account.

2. Housing allowance. As a rule, house rentals paid by urban residents should include house depreciation (calculated on an average of 50 years), house repair expenses, and housing service expenses. At the end of 1980, housing for residents totalled 49 million square meters in the municipality. If the above expenses and depreciation were taken into account, 347 million yuan in house rentals should have been collected. House rentals now collected by various management departments amount to only 37 million yuan (equivalent to only half of the house maintenance fees), and state subsidies amount to 310 million yuan or 90 percent of the house rentals that should have been collected. On average each resident gets an allowance amounting to 61 yuan. To be sure, as housing levels are not even, those households occupying less living space get a little less allowance than those occupying a little more.

3. Cultural, educational, and health spending. It is preliminarily calculated that cultural, educational and health spending in the municipality totalled 985 million yuan (excluding rural outlays) during 1980. The total includes 415 million yuan in educational spending (including educational costs, depreciation and maintenance expenses on schools), 310 million yuan in health service spending (including free medical service), 80 million yuan in cultural and physical culture spending, 180 million yuan in costs of running nurseries, kindergartens and other collective welfare projects. Benefits averaged 193 yuan per capita.

4. Public utilities expenditures. Municipal expenditures on urban maintenance (including roads, water supply and drainage, gas and thermal power, electricity, communications, gardening, afforestation, environmental protection) and depreciation of public facilities totalled 351 million yuan in 1980, averaging 69 yuan per capita of the urban population. Some of these costs have less direct bearing on each resident but are defrayed for the benefit of all urban residents.

FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

PREFACE TO SERIES ON ECONOMIC REFORMS

HK141500 Beijing JINGJI GUANLI in Chinese No 6, 15 Jun 81 p 15

[Preface by JINGJI GUANLI editorial department to Part I of special collection of articles on reforms of economic management systems--dated May 1981]

[Text] Initiated by the leading comrades of the State Council, the industrial-economic research institute of the Chinese Academy of Social Sciences and the Sichuan Provincial Social Sciences Research Institute jointly convened a "forum on theoretical and practical issues in reforming economic management systems" in Chengdu from 16 April to 25 April this year. The forum was attended by 351 comrades from all over our country, who include economic theoretical workers, practical workers from economic departments and comrades from experimental enterprises.

This academic forum did not aim at true theoretical discussion. It aimed to study some significant theoretical and practical issues on the basis of summing up practical experiences. At the opening ceremony, Comrade Ma Hong [7456 3163] communicated the gist of the recent speeches of the leading comrades of the State Council as well as the requirements of the forum, and Comrade He Haoju [0149 6787 3513], Sichuan Provincial Party Committee secretary, addressed the forum. During the forum, Comrade Lin Ling [2651 0407] presented a special report entitled "Situation of the Reform of Economic Systems in Sichuan Over the Past 2 Years and Some Tentative Ideas About the Future," and Comrade Jiang Yiwei [5592 0001 5517] delivered a speech to the whole forum entitled "The Essence of the Reform of Economic Management Systems Is To Realize Socialist Economic Democracy."

The forum received more than 120 theses and informational items. The comrades at the forum were divided into groups to specially discuss in certain issues such as: the goals and steps taken in the implementation of economic readjustment as well as corresponding measures of reform; the increase in enterprises' decisionmaking power and the correct handling of the economic interests of the state, the enterprise and the individual; the substitution of taxes for profits and assuming sole responsibility for profits and losses; the improvement and strengthening of party leadership in reforming the enterprise leadership system; industrial reorganization and the integration of enterprises; regulation by planning mechanism and regulation by market mechanism, and so on. The discussion groups put forward some constructive ideas for the reference of leading departments concerned.

During the forum, the principle of letting a hundred flowers blossom and a hundred schools of thought contend was adhered to. The comrades attending the forum related theory to practice, freed themselves from old ideas and spoke freely. At the close of the forum, Comrade Ma Hong made the concluding speech.

The things discussed at the forum and the theses and informational items received will be selected and published be various newspapers and magazines. Our journal has resolved to devote special attention to publishing a number of important articles for the reader's reference. These articles will appear in issues No 6 and No 7 in the form of a special collection. Because space is limited, some articles have been abridged and the titles of some articles have been altered. We wish to express our apologies to the authors concerned and the reader.

PRC JOURNAL ON CURRENT ECONOMIC READJUSTMENT

HK141510 Beijing JINGJI YANJIU [ECONOMIC RESEARCH] in Chinese No 6, 20 Jun 81 pp 3-8

[Article by Xu Di Xin [6079 3321 2450] dated March 1981: "The Current Problem of Economic Readjustment in China"]

[Text]

I

At the beginning of 1979, viewing the actual condition of our national economy, the CCP and the State Council made known the guideline of "readjustment, reform, rectification and improvement." Readjustment is the center as well as the dominant part of the guideline. In the winter of 1980, our party and country once again made the statement that further adjustment of the national economy was to be made. The reason was that despite 2 years' hard work, which brought preliminary achievements as a result of readjustment, we did not attain the results that we had expected.

Disproportions in our national economy occurred as early as the latter part of the 1950's. The great leap forward movement was its prelude. At that time, the slogan for industry was "take steel as the key link" and for agriculture, "take grain as the key link." Considering the actual conditions of our country, the approach of developing steel and grain can hardly be criticized. Without steel, industry cannot take a single step forward. The lack of grain will cause problems for the people's livelihood. Nonetheless, what happened later on was the isolated development of steel and grain. Steel was developed to the exclusion of other industries, and at a later stage steel was developed at the expense of light and textile industries. Likewise, grain was produced to the exclusion of the development of forestry, animal husbandry, household sidelines production, and fishery. In such conditions, how was it possible to keep the various sectors of the economy in balance? What could possibly happen but the worsening of the disproportions in the economy?

In terms of the relative proportions of the various industrial sectors, the light and textile industries that produced the faily necessities of the people were pushed way down to the bottom of the list due to the weight of the heavy industries. Furthermore, the heavy industries provided services mainly to themselves without giving adequate services to agriculture nor to the light and textile industries. To make things worse, the internal proportions of heavy industry were also out of balance. In addition to steel, the machinery industry and other manufacturing industries were also developing too rapidly. This was not in line with the development of the energy and raw material industries. Besides, in other individual industries, there also arose the problem of disproportion. For example, both the ferrous and nonferrous metal production capacity exceeded the ore mining capacity. In the case of coal and petroleum, there was disproportion between excavation and stockpiling. In the case of light and textile industries, there was not only disproportion in relation to the heavy industries, but also shortage of supplies in relation to the domestic market and to the needs of the export trade. In recent years, blind construction of plants took place in some places, which led to scrambling for raw materials and contending for markets. Cases of small plants edging out large ones and technologically backward plants edging out advanced ones (especially in the tobacco manufacturing industry) have appeared. This has aggravated the contradictions all the more.

The disproportions of the various sectors of the national economy are closely related to those of accumulation and consumption in terms of national income. By accumulation we mean that part of the national income devoted mainly to expanded reproduction. Consumption is the remainder of national income used to meet the cultural and daily needs of the members of the society. In the past, roughly speaking, the accumulation funds were expended mainly on the capital construction of heavy industries. During the first 5-year plan, the accumulation rate was 24 percent, and industrial and agricultural output increased steadily year by year, and the people's living standard improved year by year. From 1958 to 1960, the accumulation rate was increased sharply to more than 30 percent, and the rate was boosted in 1959 to as high as 44 percent. The outcome was to throw the whole national economy into disproportion, led by the decline of agricultural output, followed by the sharp decline of light and heavy industrial output. Starting in 1961, after several years' adjustment, the accumulation rate was gradually decreased to less than 25 percent. By 1965, the national economy was approaching equilibrium, with production of the various sectors improving year by year and the living standard of the masses of the people [words indistinct] point of improvement suddenly came the turmoil which lasted for 10 years. From 1970 onward, the accumulation rate was above 30 percent. On the one hand, the so-called "Theory of sole importance of the productive force" was criticized, and there was an upsurge of egalitarianism. As a consequence, the production of the means of subsistence was less and less able to meet the needs of the masses of people. For other reasons as well our national economy in 1976 was already on the brink of collapse. During the 2 years immediately following the smashing of the "gang of four," as the "leftist" guiding thinking of getting quick results still prevailed, the accumulation rate was still maintained at a high level. In 1978, the rate was as high as 36.5 percent, new techniques and equipment were imported from abroad on a large scale, and capital construction undertakings were continuously expanded. Consequently, the problem of disproportion became more and more serious. With respect to such conditions, if readjustment measures are not taken, the contradictions and difficulties resulting from disproportion will inevitably hamper the successful progress of expanded reproduction. Under such conditions, even simple reproduction is hard to maintain. We should question: How can production capacity be formed if the construction front is extended so far that the capital construction projects cannot be completed for long period of time? How can the factories start up production if they do not get raw materials and power supply for a long period of time? How can the needs of the general masses of people be met with respect to the means of subsistence, if adequate development of agriculture and light and textile industries is not maintained for long periods of time?

Long-term economic disproportions are in sharp contradiction with the requirements of the law of developing the national economy in accordance with proportions and planning. If the disproportions are allowed to go on unchecked, it will be impossible for us to carry on successfully our modern socialist construction. Some people would say that in order to realize the modern socialist construction of our country, priority must be given to the development of heavy industries or to the production of the first category (means of production). This assertion cannot be regarded as groundless. However, if this assertion is taken to be absolute and considered in isolation, mistakes will lie ahead for us. In fact, it is not only necessary that the production of the means of subsistence should not lag behind that of the means of production. Marx said: "If things are to be carried on in a normal manner, Category II should have a faster accumulation than Category I; otherwise, the part of I (V plus M) intended for exchange with commodity IIC will grow faster than IIC, the only group in which exchange is feasible for it. ("Das Kapital," vol II, People's Publishing House, 1973) Lenin in his "Reply to Mr P. Nezmdanon" made the following comment: "In the final analysis, the production of the means of production is necessarily connected with that of the means of subsistence, as the means of production are not produced for their own sake but for satisfying the growing needs of the industrial sections producing the means of subsistence. ("Complete Works of Lenin," "Reply to Mr P. Nezhdanov" vol 4, p 142) Our mistakes in the past 20-odd years have their origin in the violation of this principle. The question should be asked: In the case of emphasizing accumulation and neglecting consumption, giving priority to capital construction without giving due attention to production, and in the case of emphasizing industry and neglecting agriculture, or in industry itself of emphasizing heavy industry and paying inadequate attention to light industry, what point can we find in common with the teachings of Marx and Lenin regarding the interrelationship between the two categories of socialist production? This one-sided practice of seeking quick results is an outcome of subjective left-inclined thinking, which is in opposition to the economic theories of Marx and Lenin.

Under the socialist system, as the means of production are put under the socialist ownership system, and as the "volume of social labor time devoted to the production of certain products are correlated to the scale of the social needs demanding such products," planning becomes feasible for the national economy. ("Das Kapital, vol III, p 209) Consequently, knowing the harmfulness of the leftist line, through the socialist system itself people will be able to readjust the proportions and bring the various sectors of the economy to a new equilibrium. Lenin once said, "Keeping things in balance constantly and conscientiously is planning in the real sense." ("Non-Criticizing Criticism." "Complete Works of Lenin," vol 3, p 566) In 1979, our party and government began to implement the eight-character guideline with readjustment as the center. This is a concrete manifestation of what Lenin referred to as the "conscientiously maintained equilibrium." In this respect, we have already gained preliminary achievements. In 1979 and 1980 the proportion of light industry in total industrial output was gradually increasing. Its proportion in 1979 was 43.1 percent and in 1980, 46.9 percent. Its accumulation rate in 1979 came to 33.6 percent, a reduction of 2.9 percent compared with the previous year. In 1980 it was about 31 percent, again a reduction of 2 percent in relation to the previous year. In curtailing the capital construction front, results have been gained day by day. In 1979 and 1980 a group of large- and medium-scale projects was stopped or construction of them was suspended. In the meantime, the people's livelihood has been improved. The peasants' allotted earnings from the collective averaged 83.4 yuan in 1979, an increase of 9.4 yuan in comparison with 1978. In 1980, it was 85.9 yuan, an increase of 2.5 yuan compared with 1979. In 1979 the average wage of workers under the system of ownership by the whole people was 705 yuan, an increase of 61 yuan as compared with 1978. In 1980 it rose to 803 yuan, an increase of 98 yuan as compared with 1979. In 1979, total resale value of commodities of the society topped 180 billion yuan, an increase of 24.1 billion over the 1978 figure. The 1980 figure was 214 billion, an increase of 34 billion over the 1979 figure.

Practice is the only criterion for the judging truth. As practice indicates, in order to readjust the proportions of the various sectors of the economy, first of all a correct readjustment must be made to the relation between accumulation and consumption. This means the share of national income occupied by accumulation must be controlled. According to the experiences of our country in the past 30 years, maintaining accumulation at the level of 25 percent is an appropriate ratio. Doing so not only keeps the supply of the means of subsistence and the needs of the people roughly in balance but also prepares the material (funds) condition for curtailing the capital construction front. The capital construction fund constitutes an important part of the state's budgetary expenses. A reduction of the capital construction fund expenses (of course, corresponding cuts should be made in regard to defense expenditures and administrative expenses), enables the state financial authorities to bring the financial revenues and expenses as well as the bank credit payments and repayments gradually into balance. Once the government's financial receipts and disbursements as well as the bank credit payments and repayments are in balance, the demand and supply of products of the society, in terms of their total vlume, will be brought into balance. As a consequence, prices will be stabilized step by step.

Some people think that readjustment in our country is a passive guideline. This viewpoint is not in conformity with facts. Our readjustment does not imply retreat for every sector of the economy but retreat for some and advancement for others. For example, the metallurgical industry, the machine-building industry and certain other industries are to be temporarily curtailed, while the light and textile industries, the energy, communications and transportation industries as well as the sectors of sciences, education, culture, sanitation and so on are to be further developed within the supply and financial capabilities of the state. In short, for those in which retreat is necessary, retreat must be carried out in full. For those in which development is necessary, development must still be carried out. Even for those in which retrenchment has been carried out, it is done for the sake of advancement to the next step in order to gain an active position for the situation as a whole. Therefore, our readjustment is not a passive but an active guideline with strategic significance.

Some people are skeptical about our readjustment program, of whether or not it will be a success. We do admit that achieving economic adjustments is no easy task. First of all, we must reason with, convince and educate those cadres who take no notice of the whole situation and cling to their factories which consume large quantities of energy and raw materials and turn out low-quality products. Secondly, we must do good work in the aftermath of the closure of and stoppage of operations in some plants as well as the cancellation and postponement of some construction projects, project and maintain well the plants, equipment, raw materials, fuel, products and other assets belonging to the state. Third, we must do well in making arrangements for the workers of the closed and suspended plants as well as for those of the canceled or postponed construction projects. The mending tasks involved in the readjustments certainly are not limited to the items just mentioned, but these items alone will mean a substantial workload, and the problems involved are complicated. Nevertheless, if we handle the problems correctly in accordance with the policy of our party and country, carry out elaborate propaganda work, persist in taking the mass line and seriously execute the socialist law and discipline, things can be done well. In 1979 and 1980, the very fact that the large- and medium-size construction projects which we canceled numbered several hundred is evidence of this. For these reasons the skeptical view about the success of the readjustment of our national economy is groundless.

II

Readjustment is mutually related to reform, rectification improvement and they promote one another.

By reforms, we mean reforms in economic management. There are roughly 6,600 enterprises in our country which have taken part in practicing expanding the decision-making power of the enterprise. Of these, 191 enterprises are trial points for "substituting taxes for profits, independent accounting and responsibility for one's own profits and losses." The overwhelming majority of these enterprises have obtained comparatively good results since the reforms. However, due to the disproportions of the national economy, complete elimination of the difficulties has not yet been achieved. As a result, the overall implementation of the difficulties has not yet been achieved. As a result, the overall implementation of the reforms has not been possible. Why is this so? First, as mentioned above, the essence of the reform lies in the delegation of power to the lower authorities, but readjustment of the economy calls for the strengthening of the concentrated and unified management of the economy by the party Central Committee. It is quite obvious that without the unified leadership of the party Central Committee in economic affairs, it is difficult to carry out the curtailment of the capital construction front, the reduction of the production of goods in excess supply and excessively high in proportions as well as the development of the production of goods in short supply and in excessively low proportions. Consequently, we must deal with the contradiction between readjustment and reform, undertake readjustment first followed by carrying out reforms. Second, one important aspect of the reform of economic management is to replace the unitary and instructive plan adjustments by adjustments that rely mainly on regulation by planning mechanism supplemented by regulation by market mechanism. However, to give play to the function of the market as regulator, normal supplies and sales are prerequisites. Under the condition of serious disproportion, as the total demand for the means of production and that for the means of subsistence far exceed total supply, there is no concern about the marketability of poor-quality, high-priced commodities which are nevertheless in short supply. This being the case, how can the reform of management be undertaken? Third, as a result of disproportion, many enterprises face constant short supply of raw materials, fuel and electrical power, and quite often they are forced to stop or curtail production. If these external problems are not solved, it is very difficult to carry out the reforms intended for the enterprises, for example, independent accounting, responsibility for one's own profits and losses, performance evaluations and so on. However, we must say that during the period of readjustment, even in the absence of reform of the management system, certain reforms that are beneficial to readjustment should still be actively carried out. In the long run, reform and readjustment are not in opposition to each other. Good performance in the reform of the management system will consolidate the fruits of readjustment.

Rectification refers to closing, suspending, merging or shifting the production of those factories which have developed blindly and which have suffered from excessive consumption and financial losses for a long time. In this regard, rectification and readjustment mean the same thing, because closing, suspending, merging or shifting the production of blindly developing factories with excessive consumption and financial losses for a long time can mean readjustment as well as rectification. Aside from this, converting the "large and complete" and the "small but complete" setup of the past to the form of cooperation according to specializations can also mean both readjustment and rectification. However, rectification for the enterprise is not always identical to readjustment with respect to the national economy. As mentioned above, readjustment of the national economy mainly refers to the disproportions among the various sectors. Rectification of the enterprises means more than closing, suspending, merging and shifting and reorganization. It can also mean tapping potential and carrying on renovations and transformations of the existing enterprises in order to enhance the production and technological standards of the enterprises. This means improvement of the operations and management of the enterprises (including improving existing enterprises, especially those with chaotic management, through rectification), enhancing product quality, increasing product varieties, reducing production costs and improving economic efficiency. In the meantime, new technology imported from abroad will by and large be utilized in the existing enterprises. In order to facilitate the takeover by the new technology, it is necessary to improve the technical capacity of the original plants as well as to improve their operations and management.

By improvement, we mean increasing labor productivity and economic efficiency. Through readjustment, reform and rectification, it will be possible for us in carrying degrees to improve the technological standard, the operations and management standard as well as that of the development of the productive force of the various sectors of the national economy. At present, we have nearly 400,000 industrial and transportation enterprises, a considerable part of which have improved in varying degrees their work efficiency as well as economic efficiency through reform and rectification. However, we are not complacent with the success we have achieved. Lenin once said: "In the final analysis, labor productivity is the most important and principle thing with respect to assuring victory for the new social system." He also pointed out: "Socialism will produce a new and much higher level of labor productivity" ("The Great Pioneering Work," "Selected Works of Lenin," vol 4, p 16). The purpose of our demanding that enterprises increase labor productivity is to transform the latent possibility of the superiority of the form of socialist production into reality.

III

At present, we are keeping a firm grasp on readjustment for the following reasons: to solve the problem of disproportions among sectors of the national economy, the disequilibrium between government budgetary receipts and disbursements as well as between credit payments, and repayments and between commodity supply and demand; and to prepare a solid basis for reform, rectification and improvement. That we must do well in solving these problems is indisputable. However, we should not limit our horizons to this area alone. We should broaden our horizons. To put it more concretely, it is necessary as well as possible for us to treat the path of Chinese-style modern socialist construction.

The first problem concerns the rationality of the economic structure. As mentioned above, theoretically the economic structure of our country has been in the order of agriculture, light industry and heavy industry for the past 20-odd years, but in reality heavy industry was given so much weight that it prevailed over agriculture and light industry. This situation not only explains the disproportions among agriculture, light industry and heavy industry but also gives rise to a more serious problem: The undue emphasis given to steel in heavy industry, the illusion that steel means everything and all other sectors must make room for steel. We certainly do not underestimate the important role of the steel industry in the national economy. Nonetheless, if this important role is exaggerated without limit, we will be bogged down in absurdity. The purpose of socialist production is not production itself but satisfaction of the growing physical and cultural needs of the broad masses of people. Likewise, the production of steel certainly is not for the sake of steel itself but for the production of machines that turn out consumer goods and ultimately for the satisfaction of the physical and cultural needs of the people. The structure of our economy can be regarded as rational only when it manifests the socialist purposes of production. Only by making the structure of our economy a rational one can the superiority of the socialist economic system be shown, the physical and cultural life of the general masses of people be improved day by day, and the further development of agricultural and industrial production be pushed forward through enhancing the socialist initiative of the masses of people.

The second problem concerns the rational operation of the enterprises. After readjustment, reform, rectification and improvement, the state enterprises and the urban collective enterprises of our country will give more play to the capacity of their technical equipment as well as accelerate the turnover of the circulation funds, and enable the enterprises to gain better economic results with fewer fixed assets and circulation funds. This is the requirement of the economic law of least consumption for the best results. Now, the fixed assets of our country are by no means small in amount, but their economic efficiency is quite poor. In 1978, in the case of state enterprises of the country as a whole, the ratio between the total value of their fixed assets and that of their output came to 1:1.22, while in developed countries the ratio was about 1:3. If such a situation remains unchanged, it will be very difficult for us to provide our country with more and more physical wealth, to supply our people with more and more consumer goods and to supply the society with an abundant accumulation fund. In order to change this situation, we must eliminate waste, reduce costs, guarantee quality in production, accelerate turnover and reduce the overstocking of commodities.

The third problem is to realize the integration of regulation by planning mechanism and regulation by market mechanism. This is a very important part of readjusting the proportions of the various sectors of the national economy. Its task is to provide a solution to the problem of the disjoining of production from needs as well as the cutting off of supplies from needs. Regulation by planning mechanism refers to the function of the law of developing the economy according to proportions and plans. Regulation by market mechanism refers to the function of the law of value. In essence, the integration of plan and market regulation means the combined application of these two laws. Is this possible? Some people who say the two are in opposition are skeptical about this possibility. Marx once said: "For the production of each specific commodity, the law of value of commodities determines how much of the total labor time at the disposal of the society can be devoted to it." ("Das Kapital," vol I, p 394) That is to say, the total social labor time must be allocated proportionately according to the social needs among the various production sectors. The law of the planned development of the national economy shows this objective proportion from the positive side, while the law of value shows this relation from the negative side. If our plans violate the objective proportions, the blind spontaneous effects of the law of value will play their role "silently" from the negative side. In this situation one can see the effects of the two laws, and this transition demonstrates of their consistency. The reason why plan and market regulation can be integrated is found in the consistency of these two laws. In order to put into effect the integration of plan and market regulation in relation to the arrangement and allocation of supplies, it is not only necessary to take into consideration the proportions of the various sectors, but also to fix production according to sales and to fix supplies according to production in the light of the possible needs of the market so that an equilibrium between production and sales can be achieved or nearly achieved. Will the state planning organizations from now on completely stop issuing instructive targets to the various economic departments and leave the whole thing to the play of market regulation? In my opinion, since our country is a socialist country, it is inevitable that plan regulation plays the guiding role in our production and construction. Therefore, instructive targets must still be implemented when necessary. The present situation calls for the appropriate reduction of instructive targets. In the meantime, some reference targets are to be transmitted. In both cases, be it instructive targets of reference targets, what should be shown is the objective needs, and production for the sake of production should be avoided. In order to integrate plan and market regulation, it is not only necessary to reduce appropriately the instructive targets but also to improve the state monopoly for purchase and marketing in the commercial sector (of course, speculative activities in the country fair trade should be banned). If we can do all these in a reliable and honest manner, the past situation of producing for the sake of producing and the state monopoly in the realm of circulation will be changed, and in their place will emerge the lively prospect of commodities finding level of demand and of goods circulating without obstacles.

Some people think that placing market regulation in a high position comparable to that of plan regulation degrades the law of developing the national economy according to plans, and this implies retrogression of socialism to capitalism. I think that this viewpoint is groundless. Is it a retrogression to capitalism? This depends on whether or not the means of production of socialist ownership overwhelmingly predominate in the national economy. If the socialist ownership still predominates overwhelmingly in the national economy, and if the products under the plan of state regulation still play a guiding role in the production of agricultural and industrial products of the whole country, on what ground can we say that our national economy is going backward to capitalism?

Finally, it should be noted that implementing the guideline of readjustment, reform, rectification and improvement is the first battle in the realization of our modern socialist construction. Facts will demonstrate that the implementation of the eight-character guideline of readjustment, reform, rectification and improvement will pave the way for China's modern construction. Here, a few words about Chinese-style modern construction are quite necessary. The first step of China's modern construction is to reach the goal of becoming a relatively "well-off" society by the end of this century and then gradually increase the degree of modernization on this basis. In order to achieve this, we need to assimilate the advanced technologies of the Western countries in the field of enterprise management. For this reason, some people think that carrying out modernization of China means Westernization of China. I do not think this viewpoint is tenable. China is undertaking its modern construction on the basis of a socialist system and no on the basis of a capitalist system. Even if we permit the existence of individual economy and joint venture enterprises of Chinese and foreign capital, the foundation of the Chinese socialist system will remain intact. As for the public presentation of Chinese-style modern construction, it is done in the light of the actual condition of China. The actual condition of China can be characterized by its large population (mostly peasants) and weak foundation. In 1949, when our country was just liberated, our population was 540 million. By 1978, the total population (not including that of Taiwan Province) rose sharply to close to 960 million. The excessive population growth represents a retardation of the gradual improvement of the physical and cultural life of the masses of people on the one hand. It impedes the successful progress of the socialist accumulation and construction of our country on the other. Moreover, the modern development of industry and agriculture will necessarily bring about the improvement of the composition of production technology. Consequently, comparatively more funds will be devoted to investment in equipments and technology and less to the needs of labor (especially simple manual labor). The more developed the modern socialist construction, the more acute this contradiction will be. For this reason, the Chinese-style modern construction must be developed in close association with birth control measures. In order to solve the problem of youths anticipating employment and the growth of the new labor force, while promoting the development of the modern agriculture, energy, communications and transportation (after readjustment, with the achievement of general equilibrium of the national economy, the steel, machine-building as well as other industries are still to be developed according to certain proportions), labor intensive industries and the traditional arts and handicrafts must be developed. In addition to these, service industries sought by industrial and agricultural production and by the people for their daily necessities must also be developed. The development of various service industries will be an indispensable part of the improvement of the people's lives. In this regard, special attention should be given to the role of collective enterprises, and the individual economy must be permitted to exist and grow within specified limits.

Before liberation, China was a semifeudal and semicolonial country, quite backward in industrial, agricultural, scientific and technological development. When we speak of our weak foundation, by and large, this is where the weak foundation lies. Gratifying achievements were achieved as the result of hard work in the 17 years following liberation. However, with the 10 years of instability and turmoil that ensured, the standard of science and technology of our country has lagged further behind in comparison with the top standard of the world. As indicated by practice, long-term accumulation is needed to enhance national strength, and the training of scientific and technological personnel also requires long-term efforts. Consequently, good results cannot be achieved if we neglect the actual condition of our country, give way to impatience and proceed rashly. Therefore, Chinese-style construction must advance steadily, and steadiness does not mean marking time but bigger progress in the future.

ECONOMIC PLANNING

ECONOMIC JOURNAL ON MARKET REGULATION

HK140826 Beijing JINGUI GUANLI in Chinese No 6, 15 Jun 81 pp 64-67

[Article by Song Yangyan [1345 7402 8827]: "How To Strengthen Planned Regulation by Market Mechanism"--note passages within slantlines denote boldface type]

[Text] The regulation by market mechanism so often referred to in fact refers to certain economic laws governing the market (mainly laws of value), the production scale of the various types of commodities as it is regulated by price, profit and other such mechanisms, the sufficiency of assets and the labor force, and the profit distribution process. Viewed as a whole, regulation by market mechanism is the rational, that is proportional, distribution according to social needs of all labor in society among the various different sectors of the national economy so that it can be effectively utilized.

In a commodity economy based on a public ownership system, the regulatory effect of the market, generally speaking takes place behind the producers' backs, that is, in a situation where it is unknown or not too clearly known, or not utilized or not fully utilized. With the advent of a socialist society and the establishment of public ownership of the means of production, the regulatory effect of these economic laws governing the market is, generally speaking, more easily recognizable and consciously utilized according to its demands. Thus the former is known as spontaneous regulation by market mechanism, while the latter is known as planned regulation by market mechanism. Under socialist conditions, a purely "free market" does not exist. Judging by development trends, the planned nature of regulation by market metchanism will be increasingly strengthened. Planned regulation by market mechanism will play an increasingly greater role in socialist production, exchange, distribution and consumption. Therefore, when dealing with socialist construction, we must on no account neglect to conscientiously study and fully recognize and utilize regulation by market mechanism.

We have been carrying out a reform of the system for over 2 years and this has proved that the implementation of planned regulation by market mechanism has achieved clear economic effects. However, many problems have also emerged which need to be studied and solved. Our present task is to further improve and strengthen planning guidance for regulation by market mechanism by investigating, studying and summing up our experience, so as to bring into fully play the promotional role of regulation by market mechanism. If we are to deal specifically with the various problems that cropped up in our past attempts at regulation by market mechanism, I think we must conscientiously tackle the following:

//First, we must readjust the industrial structure and develop in a big way commodity production, particularly production of everyday consumer goods, which forms the material base for bringing the effect of regulation by market mechanism into full play.//

If we are to bring the advantages of regulation by market mechanism into full play, we must first have an abundant supply of commodities. Due to our past erroneous policy of giving priotity to the development of heavy industry and of "taking steel as the key link," we brought about a heavy production structure centered on heavy industry, particularly the iron and steel industry, and wasted and caused to lie idle vast amounts of inanimate and animate labor at intermediate points in the production process and on intermediate products, with end products, particularly individual consumer goods, being a rarity. This is the main reason why supply of many commodities has failed to meet demand for so long and it has also caused or encouraged inflation and prevented any speedy improvements of the people's lives. How can we change this situation? Merely relying on the method of "curing the head when there is a headache and curing the foot when the foot aches" will not alleviate the problem, since the most important thing is to "cure the root." That is to say, we must resolutely transform the heavy industrial structure centered on heavy industry, particularly the iron and steel industry, which gradually came into being over the years, into a light industrial structure genuinely centered on agriculture and light industry. Only on this way can we raise economic effectiveness, step up production and expand commodity supply. Only a continuous growth in production can form a firm material base for the development of the socialist market and the bringing into fully play of the advnatages of regulation by market mechanism.

//Second, we must increase circulation channels, develop circulation forms, decrease circulation links and construct more circulation networks.//

Since the basic completion of the three great restructurings, we are basically left with two types of commerce in our country: state-run commerce and collective commerce. Later, because of the emphasis of speeding up the transition, collective commerce was run more and more like state-run commerce. Therefore, within the sphere of the circulation of commodities, practically everything was monopolized and turned into state-run "official commerces." Thus the circulation of commodities was hindered and the market stagnated, causing many small commodities to become more and more scarce, the quality of commercial services to drop and the masses to suffer inconvenience in their lives. Therefore, the urgent task at the moment is to thoroughly smash the monopoly of state-run "official commerce," develop in a big way the collective commercial economy, develop individual small retailers, rural country fair trade and urban agricultural trade markets, jointly-run commerce, and so forth. We should also ensure that each has a role to play, that each is given the chance to display its abilities, that the skills of one make up for the shortcomings of another, that they are well coordinated with one another, and that full play is given to the role of a unified socialist market made up of various economic components.

In a socialist market, we should, in order to speed up the flow of goods, increase forms and reduce links. As for the connection between industry and commerce, in order to ensure that industry caters for the market and produces according to need, apart from an extremely small minority of commodities for which we can retain the system of state monpoly for purchase and marketing and other such forms, the commercial sector should, for the remaining majority of products, adopt a form for choosing, ordering, selling, acting as commission agent and so forth, according to the particular circumstances. There is also one section of commodities that can be sold by the industrial sector itself. We should thoroughly do away with the system of state monopoly for marketing.

As for the connection between agriculture and commerce, we can, for important commodities like grain, oil, cotton, and so forth, that affect the national economy and the people's livelihood, retain for the present the system of state monopoly for purchase and marketing and of dispatching to purchases, but for ordinary agricultural sideline products, we should adopt a system whereby purchases and sales have to be negotiated and the quantity, quality, price, and so forth are all laid down by the buyer and seller face to face, and implement flexible and varied forms of buying and selling. We can permit certain agricultural sideline products to be sold by the peasants themselves. As for certain staple products in short supply which act as industrial raw materials, the state should continue its system of planned buying. We should allow certain industries and enterprises to proceed directly to the villages to purchase the agricultural sideline products that they require, including any special means of production. We should also allow peasants (including the collective or the individual) to take their products, particularly certain fresh, live commodities, directly into towns for sale by themselves.

As for the connection between commerce and commerce, we must resolutely transform this relationship (including the relations between the upper and lower ranks, wholesales and retailers, and one shop and another) into a relationship whereby the buying and selling of commodities is carried out in accordance with the principle of exchange at equal value.

Within industries, certain commodities can be directly bought and sold between one factory and another. There is no need for a commercial middleman. Between places where raw materials come from and places where they are processed, contracts can be directly signed, economic ties established and commodities exchanged.

At the same time, in order to adapt to the development of commerce and the needs of commodity circulation, we also need to restore warehouses, trading companies, trust companies, exchanges and the many other kinds of commercial institutions. We must also develop cables, telephones, correspondence and other such businesses facilitating the placing of orders. We must devote major efforts to the launching of various kinds of merchandise ordering meetings, sales exhibitions and other such activities.

In order to develop the socialist market, speed up the flow of goods and make the lives of the people more convenient, we still need to devote major efforts to constructing more commercial and service networks. Apart from devoting major efforts to developing collective and cooperative commerce together with individual small retailers, within the confines of policy, certain state-run commercial units should, provided they have the appropriate conditions, also change from large into small and split up from one unit into several units, and diffuse wherever there is space until they have penetrated into the countryside, including remote mountain and pastoral areas. We must launch competitive and emulation activities among the various commercial forms and networks, genuinely liven up commerce and promote a prosperous and flourishing market.

For the moment, in order to strengthen regulation by market mechanism, we still have to train a contingent of commercial staff and workers who ardently love commerce, are proficient in professional work and engage in their trade in a civilized way.

To sum up, we should not block up, but only unblock the socialist market. This should be foremost in our minds if we are to liven up circulation and stimulate the market without creating confusion.

//Third, we must reform our present price management system, carry out a rational step by step readjustment of the pricing setup and skillfully use tax revenue, credit loans and other such economic levers to ensure that economic activities develop along the correct path.//

Prices are the main mechanism in the implementation of regulation by market mechanism. If we do not establish a rational pricing setup, it will be hard to bring the advantages of regulation by market mechanism into play. There are at present many problems inherent in our country's pricing policy, for example, the prices of many commodities are severely divorced from their value; there exists among ~~many~~ commodities the phenomenon of grossly irrational price parities; there are many commodities whose prices have been frozen for a long time, not shifting when they should; plans have controlled prices too rigidly, management has been over too wide an area and so on. It will be hard for us to completely solve all these problems during our short-term readjustment and reform. Particularly in the present period of readjustment, in order to stabilize prices and the people's lives, we should not yet carry out too great a readjustment or reform of the commodity price system. But it should be made clear that, during readjustment, certain minor readjustments and reforms are not only possible, but also necessary. For example, during readjustment, we can, in respect of certain industrial goods, first readjust exfactory prices, wholesale prices and the prices of intermediate products. Because these readjustments are merely the redistribution of profits among trades, sectors and enterprises, they do not greatly affect state revenue or the people's lives. During readjustment, the prices of certain means of production, like ordinary electrical products, bearings, tires and other products in full supply, may be lowered as warranted by the circumstances. Among petroleum products, the price of crude oil and heavy oil may also be lowered as warranted by the circumstances. Among the industrial products needed by the people in their everyday lives, we should resolutely carry out a readjustment of those which could cause prices to drift downwards. We must adhere to the principle of selling more on a narrow profit margin and oppose the concept of selling less at higher prices. We must explore the market and step up production.

Moreover, although at certain times and within certain limits, it may be necessary to adopt a policy of limited financial subsidies, this should never be considered a long-term plan, because such a path would narrow in on us, forcing us that at present, we are spending several billion yuan annually on subsidies for the means of production alone, add to this the agricultural water and electricity subsidy and the import subsidy, and the figure would be quite considerable. Judging by developments, if we do not make efforts to put an end to or change this situation, it will hereafter continue to grow year by year, which would be quite intolerable.

In order to rid ourselves of these difficulties caused by progressive increases in subsidies, we must carry out a thorough reform of the pricing system. At present, apart from losing no time in carrying out the necessary readjustment of the prices of certain commodities as far as conditions will allow, we should also pay close attention to the carrying out of a systematic and complete reform of the pricing system and pricing setup, conduct meticulous investigation and study, and make the necessary preparations for an overall reform to be carried out at some appropriate time in the future.

For the past 2 years, we have been reforming the tax system, the method of credit loans and so forth. We have already carried out some experimentation and facts have proved that the effects are good. From now on, we must, while summing up our experience, continue to skillfully use these effective economic levers to guide midroeconomic activities. Particularly where an overall readjustment of prices cannot be carried out, it is even handier and even more necessary to make full use of the regulatory effect of the tax system and credit loans.

//Fourth, we must smash blockades and separatism, and restore and develop trade centers and trade networks.//

Economic development is necessarily subject to economic laws and at the same time is affected by historical and actual, social and natural conditions. In the history of economic development in our country, there have gradually come into being with the development of the commodity economy, numerous market centers, both large and small, often called trade centers. For example, Shanghai is the trade center of the eastern region, Tianjin the trade center of the northeastern region, Guangzhou the trade center of the southern region, and so on. Around every large trade center, there have also come into being numerous small and medium-sized trade centers. These small and medium-sized trade centers are like "myriad stars surrounding the moon," for they are active all around the large trade center, they are mutually coordinated and work together for the development and prosperity of the economy. These trade centers, due to their trade contacts, can make up for each other's deficiencies and have close working relationships with each other, thus forming a trade network embracing the whole country. Although these trade centers and networks that have come into being naturally and after the lengthy development of the commodity economy still have their irrationalities, they do on the whole meet the needs of our country's economic development. However, in the past, during the restructuring of industry and commerce and the demarcation of administrative areas, they were destroyed one by one as a result of man-made factors. As they did not correspond with the administrative divisions demanded by the process of economic motion and with the existence of administrative centers and also because of their blind involvement in economic processes, many highly strange phenomena emerged in the course of their economic activities. For instance, Wuxi and Shanghai are right on each other's doorstep. As far as economic ties are concerned, transport on water and overland routes is convenient, so they could well have established direct commercial ties. However, as far as administrative relations are concerned, Wuxi lies in the Jiangsu administrative area, so its products may not be brought into Shanghai without permission from the administrative authorities in Nanjing, products from Shanghai may not be brought into Wuxi, and so forth. What is more important is that such economic divisions and blockades preserve backwardness and prevent competition. Take for instances a toothpaste produced in a certain province. It cannot be squeezed out even if you use both hands, but toothpaste from Shanghai and other places may not be brought into the area, thus perpetuating the production of this backward product and ensuring its long-term monopoly of the market.

In order to implement and strengthen regulation by market mechanism and bring its advantages into play, we must, besides restoring step by step the trade centers and networks that have already come into being and carrying out any necessary restructuring according to socialist principles, set up and develop new trade centers and networks. For example, with the development of animal husbandry in the livestock rearing areas, we can, in certain appropriate cities in Nei Mongol, Xinjiang, Xizang and other places, set up trade centers and networks with the stress on animal husbandry products. Let us take another example. In the area around Beijing, with developments in urban construction, the completion of the numerous satellite towns will, in the environs of the Beijing municipal trade center, gradually form numerous small trade centers and networks, which will be highly conducive to prosperity and the development of the economic life of the capital.

With the restoration and development of trade centers and networks, we are sure to progressively smash the economic blockades and divisions brought about in the past by division into administrative areas. With each locality bringing its advantages into play, operating rationally, strengthening its ties and organizing jointly run businesses all according to their respective economic and natural characteristics, economic setups and divisions mutually linkedvia the market will naturally come into being. Such a setup and division, coupled with rational usage by the people, will definitely have a tremendous accelerating effect on economic construction in our country.

//Fifth, we must establish and perfect as soon as possible a channel for market news and information.//

In order to bring into full play the regulatory role of the market on production, circulation, distribution and consumption, we must, within the framework of the whole country, from the districts, localities and provinces right up to the responsible central ministry or bureau, establish as soon as possible a group of specialist market calculation and forecasting organizations. Larger specialist companies and united companies can also establish similar organizations. Moreover, we also have to manufacture and import some advance methods of market forecasting, like computers, and so on. We must also skillfully and widely employ all methods of market research, like opinion polls, sampling investigations, commodity sales exhibitions, mobile exhibitions, consumer discussions, joint meetings between producers and vendors, order placement meetings, as well as publishing magazines on market trends. We must also, with the market information at our disposal, strengthen exchange of information, set up an information contact network and expand our source of information. We must meticulously sift through, analyze and study information that we have gathered and, having drawn a conclusion, put forward opinions and suggestions, so as to provide the responsible departments with a reliable basis for deciding on policies and improving work.

Among the commercial information activities, it is highly necessary for advertising to be properly developed.

//Finally, we must also strengthen the legal system and political and ideological education.//

In talking about regulation by market mechanism, we must also consider market management, for without the necessary scientific market management, we cannot ensure that the market will be "active not chaotic." In market management work, economic methods are admittedly important, but administrative methods are no less vital. We cannot do without a legal system in our implementation of planned regulation by market mechanism. The practical effectiveness of a legal system lies in: 1. We must give legal protection to production relations that have already been suitable readjustedin our reform of the system and production forces that have been unleashed, so that they may develop healthily; 2. We must ensure that the enterprises, being relatively independent commodity producers and commodity exchangers, conduct economic activities in a normal fashion; we must subject to the sanctions of the law those who, in the course of economic activities, flagrantly violate it, like covertly raising prices, raising prices without authority, evading taxes, failing to hand over profits to higher authorities and so on; we must deal with the various kinds of economic disputes according to the law, iron out the various contradictions and ensure that the commodity economy remains active and develops normally. Now we must formulate as quickly as possible factory laws, shop laws, company laws, contract laws, tax laws, pricing laws, planning laws and so on, so that the activities of enterprises will have laws upon which to rely. Law is coercive force. If people's behavior to stay within the confines of normality, we still need to carry out education on the theme of political ideology. We must stress practical education and not allow it to degenerate into empty words. We must place emphasis on teaching the enterprises and the broad masses of laborers to bear the cardinal principles in mind and take the overall situation into account, on cultivating the concept of serving the people and overcoming departmental selfishness and petite bourgeois and bourgeois management thinking and style.

It must be pointed out whether or not, in the course of implementing regulation by market mechanism, there is absolutely no need for regulation by planning mechanism of a directive nature? Of course not. What we are opposed to is the planning of a directive nature that we had in the past which was practically "autocratic" and divorced from reality. Planning of a directive nature, as one form within the socialist regulatory system, was needed not only in the past and will be needed in the future, but is especially needed during certain, specific historical periods, like the present period of economic readjustment. Without it, we would be unable to correct, in a realtively short space of time, the disproportion caused mainly by it in the past. However, the planning of a directive nature needed today is no longer "autocratic" regulation by planning mechanism. As well as planning of a directive nature, there also exists planning of a guiding nature, as well as planned regulation by market mechanism, the product of the union between planning of a guiding nature and the market economy. Our planning work must endeavor to mutually coordinate these two types of regulation and allow them to their proper role.

REFORM OF CLOTHING PRODUCTION

HK140821 Beijing JINGJI GUANLI [ECONOMIC MANAGEMENT] in Chinese No 5, 15 May 81 pp 39-41

[Article by Gong Xiangyou [1362 4161 0645]: "The Reform of the Management System for Clothing Production"--passage within slantlines denote boldface]

[Text] With the development of China's construction of the four modernizations and the improvement of the people's living standards, people in both the urban and rural areas are increasingly demanding high-quality clothing in new and beautiful styles. Over the past few years, however, the supply of ready-made clothes in the market has always been lagging behind demand. Contradictions between supply and demand have been particularly serious in the case of medium- or high-grade clothes made of chemical fiber or woolen cloth and retail departments are slow in processing materials or supplying ready-made clothes. It is therefore a pressing demand of the masses to solve the problem of it being "difficult to buy clothes and time-consuming to have them made."

(1)

The problem of it being "difficult to buy clothes and time consuming to have them made" is due to various factors, but the main one is that over a long period of time little importance has been attached to the clothing industry. As a result, clothes, being considered as small commodities of the third category, are excluded from the production plan, and the provision of relevant raw and semi-processed materials is not guaranteed. In addition, commercial departments have all along been using the same method of having orders placed by the state with enterprises for processing materials or supplying ready-made clothes and exercising a monopoly in purchase and marketing as in the time of socialist transformation. As a result, the departments of supply, production and marketing have been seriously out of contact with each other, production enterprises do not have any autonomy and the market is put under tight control, thereby restricting the development of productive forces. Since production lacks planning, the tasks of providing services for processing materials received are not guaranteed and the workload is not evenly distributed throughout the year. During the peak seasons, the workload is excessively high and when the slow seasons arrive, there is no work to do. Because clothing enterprises cannot stay in business, the only way out is to keep switching to other types of business of other forms of production and the number of production and retail networks for processing materials or supplying ready-made clothes keeps declining. According to statistics of light industrial departments, there were 5,600 clothing enterprises under the departments of light industry and affiliated organizations throughout the country in 1979. This number was more than two-thirds less than the 21,000 clothing enterprises organized during the 1957 cooperativitation movement. In particular, the clothes processed by commercial wholesale departments are only some popular goods of dependable quality which require a long circulation period and are limited in variety, specifications and design as well as outdated in style and cannot meet the changing demands of the market. Clothing enterprises do not have the right to design, manufacture and sell their own products in line with the demands of the market, nor can grass roots shops make purchases directly from clothing enterprises. Such a system of management in which the departments of supply, production and marketing are not in contact with each other has brought about the abnormal situation of clothes lying idle in stock on the one hand but out of stock on the other.

(2)

In order to develop the clothing industry and solve for the masses the problem of it being "difficult to buy clothes and time consuming to have them made," reform in the management system of clothing production was first carried out in Shandong Province. In August 1979, the Provincial Planning Commission, Economic Commission and Financial Bureau jointly issued a notice to the effect that it had been decided to channel the production and marketing of clothes for the domestic market into the provincial plan for clothing production. The necessary dress materials would be supplied directly by textile printing and dyeing mills in accordance with the plan. Instead of having products for purchase and marketing under the monopoly of commercial wholesale departments as before, samples would be offered for selection before any purchase would be made, and factories and shops would be put into direct contact with each other. Such a reform solved the serious long-term problem at its root of having departments of supply, production and marketing out of contact with each other. Clothing enterprises could purchase dress materials and arrange production in line with the demands of the market, shops could make purchases in line with the tastes of the masses, and autonomy was allowed for both the industrial and commercial enterprises, thereby mobilizing their enthusiasm. As a result clothing production achieved rapid development, only 4 months after the reform was initiated in September 1979. By the end of 1979, the monthly output of clothing production increased by an average of 50 percent over that prior to the reform. Besides, there was an increase of over 3,000 different patterns and designs, the products began to sell well instead of lying idle in stock, and enterprises started making profits. This then changed the passive situation prior to the reform when 40 percent of the clothing enterprises throughout the province had nothing to do, the output of the clothing industry in the first quarter of the year was 28 percent lower than that of the same period in the previous year and a large number of enterprises suffered losses. But it was more important that this began to help solve for the masses the problem of it being "difficult to buy clothes and time consuming to have them made."

The good results of the reform in the system of management and administration of clothing production in Shandong Province have attracted the attention of other provinces and cities. Some of the areas in provinces like Liaoning, Hebei, Jiangxi, Gansu, Anhui, Fujian, Sichuan, Henan and so on have one after another carried out reforms after the example of Shandong Province and have all achieved relatively good results. To sum up, the results are mainly as follows:

1. /Large increase in the output of clothing production:/ In Shandong Province, the total number of clothes manufactured in 1980 was 61.5 million pieces, which was 20 percent in excess of the annual plan and 53 percent more than the 1979 figure. The volume of ready-made clothes for the domestic market alone increased by 65 percent. The net increase of clothes produced for a single year was almost 21 million pieces or 60 percent more than the total net increase for the 6 years from 1973 to 1978 prior to the reform. In Liaoning Province, a total of 44 million pieces of clothing was manufactured within the period from January to November 1980. The figure was 46 percent more than that for the same period in 1979 and the increase in the amount of ready-made clothing available for the domestic market alone was 53 percent. In Hebei Province, the reform started in August 1980; the output of clothing production for the whole year was 23.3 percent more than in 1979. In Jiangxi Province, the output of clothing production even increased by a wider margin; the 1980 output was 100 percent more than in 1979.

2. /Clothes have a greater variety of color and design, are better in quality and are selling well in the market./ The reform in Shandong Province has brought about a big increase in the variety of colors and designs of clothes. In the first half of 1980, there was an increase of 875 new varieties over that of 1979, making a total of almost 4,000 different varieties. Clothes for the domestic market achieved a passing rate of 99.7 percent and 15 varieties were assessed to be products of excellent quality by provincial standards. The sales of ready-made clothes have greatly increased because the products have a greater variety of color and design, are new in style and are saleable. Prior to the reform, commercial departments had overstocked 6 million pieces of clothing, of which 2 million pieces had to be disposed of at reduced prices. Since the reform, the output of clothing production has increased by 65 percent; both the production and the sales of clothing are vigorous, no clothing has been left lying idle in stock and supply falls short of demand. According to statistics of the Qingdao Municipal Department Store for workers, peasants and soldiers, clothing sales in the first half of 1980 totaled 1.88 million yuan which was 77 percent higher than the 1979 figure. Statistics of 19 localities and cities in Hebei Province show that there was an unprecedented increase of a total of 3,290 new varieties of colors and designs in 1980. Clothing began to be colorful and full of variations and supply could not meet demand. In 1980, Liaoning Province had an increase of 150 percent in the variety of colors and designs of clothing after carrying out the reform; the different varieties of clothing were well-received by the masses because they were good-looking in style and were in good taste. Grassroots shops reported that 1980 was a year with the best sales since the founding of the state.

Since direct supply of dress materials has been in practice, clothing factories have the autonomy to choose and order from a variety of colors and designs at the provincial textiles fair. In addition, textile printing and dyeing mills can organize production in line with the needs of clothing enterprises so that the products are saleable and less fabric is left lying idle in stock. Prior to the reform, the textile industrial enterprises in Shandong Province overstocked more than 60 million meters of fabric blends of polyester fiber and short-staple polyester because these were not purchased by commercial departments, thereby adversely affecting the production of textile enterprises. Since the reform, clothing enterprises have adopted the methods of "making delicacies out of coarse food grain," reprinting and redyeing and so on to help textile enterprises dispose of the overstocked fabric. At the same time, textile enterprises have enthusiastically improved the quality as well as increased the varieties of colors and designs of the dress materials according to the needs of clothing enterprises and have increased the supply of medium- and high-grade dress materials. As a result, a change was effected in the previous passive situation of having to process the unsaleable dress materials into clothes, which were in most cases not well-received by the masses, during the time when commercial departments were in charge of the supply of materials for processing.

3. /Both output and income have increased and the economic results are notable./ In 1980, the clothing industry in Shandong Province obtained profits of 31.52 million yuan from the sale of ready-made clothes and taxes and profits turned over to the state amounted to 33.1 million yuan, which was 85.8 percent more than in 1978 before the reform. The state, the enterprises and the workers have all got an increased income. According to statistics of 17 clothing factories in Shenyang Municipality, taxes and profits turned over to the state for the whole of 1979 when the factories processed materials received from commercial departments were only 5.15 million yuan. From January to October 1980, however, the tax and profits turned over to the state amounted to 11.4 million yuan, which was 100 percent more than the amount turned over for the whole of 1979. Hongqi clothing factory in Chengdu Municipality had processed materials provided by commercial departments into clothes for 12 years from 1967 to 1978. During that period, a profit of only 83,000 yuan was made, the enterprise was very poor and the workers earned very little. Since the reform, both production and sales have become vigorous. For the first 8 months of 1980 only, a profit of 277,000 yuan was made, which was even more than the total profits for the 12 years by over 200 percent

(3)

Practice has proved that although the reform of the management and administration system for clothing production has been carried out for only a little over a year, it has fully demonstrated its vitality and achieved fine economic results. Like other economic reforms, however, the reform in the system of the clothing business has also met quite a bit of resistance and some comrades have all along had an attitude of disapproval. This reform experience cannot therefore be spread quickly in an organized manner and even in those provinces or cities where such a reform has been carried out, there is a danger of the reform coming to a premature end. Leading comrades of the central authorities have recently explicitly pointed out: "For many years there have been different opinions regarding the reform of this system but these have never been seriously put into practice. The practice in Shandong Province has proved to be good." Therefore, in order to spread this reform, it is absolutely necessary to have a correct understanding of the reform work done by Shandong Province in the management system of clothing production, seek unity of thinking and clarify different understandings regarding certain questions in the reform.

/First, I consider that there is only one criterion, namely to look at the results from practice in order to assess whether a reform is correct and whether it should be affirmed and be popularized./ The large body of facts mentioned above clearly shows that the reform by Shandong Province in the management and administration system of clothing production has produced very good economic results. It has brought about benefits to both the state and the people and has initially solved for the masses the protracted problem of it being "difficult to buy clothes and time-consuming to have clothes made." It has also been taken seriously by the leadership and is well-received by the masses. Hence, this is a correct and feasible reform in compliance with objective economic laws and should be affirmed.

/Next, I consider that the main arguments put forth by some comrades in opposition to this reform are open to question given the facts./ There is a view that the reform in the system of clothing production must be stopped because it violates the policy of state monopoly for purchase and marketing of cotton cloth and disrupts the process of redeeming cloth coupons. In fact, reform in the system of the clothing business does not violate the policy of state monopoly for purchase and marketing of cotton cloth nor does it disrupt the process of redeeming cloth coupons. In June 1980, when reiterating the need to seriously implement the policy of state monopoly for purchase and marketing of cotton yarn, cotton cloth and major knit goods, the State Council pointed out, "since last year, when piece goods are sold in some localities and units, some cases of violating the stipulations of the state by willfully not redeeming or redeeming fewer cloth coupons have occurred." At the same time, it also pointed out, "at present, the production of cotton, chemical fiber, yarn and cloth in our country still falls far behind the demand of both the domestic market and export trade. If the situation of not redeeming or redeeming fewer cloth coupons is allowed to remain unchecked in the marketing of yarn and cloth, it will certainly disrupt the implementation of the policy to supply piece goods and redeem cloth coupons in a planned manner." Hence, in order to realistically guarantee the basic need of the people with respect to wearing clothes and using cloth, it is necessary to reiterate the principle of continuously implementing the state monopoly for purchase and marketing of cotton yarn and cotton cloth. The reform of the system of the clothing business aims at developing the production of ready-made clothes, removing the contradiction of having departments of supply, production and marketing out of contact with each other as well as solving the problem of supplying clothing to the masses, and it does not lead to the problem of "willfully not redeeming or redeeming fewer cloth coupons." This is also the case in actual situations. When practicing direct supply of dress materials and entering into contracts to supply goods, the various localities have all settled accounts and redeemed cloth coupons in accordance with the stipulations. Besides, still more than 95 percent of the clothes are sold retail through commercial departments. When industrial departments and enterprises sell some clothes retail through their own retail departments, they also redeem the cloth coupons in accordance with the criteria set by commercial departments and the situation of redeeming fewer or not redeeming cloth coupons does not happen.

/There is also the view that the direct supply of dress materials has reduced the wholesale links of commercial departments, thereby reducing the financial income of the state./ This view is not supported by facts either. Take Shandong

Province as an example. As mentioned above, the state, the enterprises and the workers have all earned more income since the system of the clothing business has been reformed because output and income have increased. In 1980, about 50 million meters of dress materials were supplied directly to clothing enterprises in Shandong Province and the amount of sales was 250 million yuan. Based on an average profit rate of 4.01 percent in the wholesale textile business, the profits from wholesale business earned by commercial departments declined by 10 million yuan, of which 5 million yuan was the 2 percent wholesale price difference reserved for textile enterprises and 5 million yuan was the amount of profits transferred to clothing enterprises. However, in 1980 the clothing business earned a profit of 31.52 million yuan from the sale of ready-made clothes in the domestic market and turned over to the state 33.1 million yuan of taxes and profits which was still as much as 28.1 million yuan after taking away from the profits the 5 million yuan transferred from commercial departments. It can be seen that the state has earned not less but more. It should be pointed out that one must not consider that only the incomes of commercial departments and not the amount turned over to the state by clothing enterprises can be called financial income of the state. A large portion of the profits withdrawn by commercial wholesale links are consumed as expenses during the course of circulation; the amount turned over to the state is not much.

/There is yet another view that since clothing is a kind of small commodity which should be produced and sold within the same locality, the clothing industry can only carry out processing of materials received from commercial departments and is not required to be channeled into a plan./ I consider that this view is also incorrect. Clothing, whether judged by the position it occupies in the life of people or by the proportion it accounts for in market sales, is a veritable big commodity and not a kind of immaterial small commodity. Clothing is even a kind of big commodity among light industrial products as its annual total output value is over 9 billion yuan which is even higher than the total output values of the "three big items" in light industry. Also, clothing has the largest export volume among the light industrial products for export and is a significant export item. It is incorrect to limit the production and marketing of clothing within certain established regions and not allow the localities to help supply each other's needs in clothing or compete against each other in the clothing business. It is a normal phenomenon for circulation volume to expand along with the development of the commodity economy. When larger quantities of ready-made clothes are produced, offering more varieties of colors and designs as well as greater variations in specifications and styles to the customers, the volume of products moving between the localities would naturally increase. This will revitalize the clothing market and is of benefit to the people. The argument of "carrying out big circulation of small commodities" is also untenable when it is used to oppose the reform of the system of clothing industry and to oppose the sale of clothing outside the area of production. Clothing can be exported and can circulate in the world market; then why can it not circulate in the domestic market? Why must the natural economy of self-sufficiency still be practiced? In fact, small commodities produced by such large and medium-sized cities as Shanghai, Suzhou, Guangzhou, Wuhan and so on are supplied to places throughout the whole country and are even exported abroad; is this not big circulation? The standpoint of encouraging the practice of commodity production and the development of commodity economy but opposing the circulation of products as well is obviously incorrect.

INDUSTRY

DECISIONMAKING IN FACTORIES

HK141446 Beijing JINGJI GUANLI in Chinese No 6, 15 Jun 81 pp 40-41

[Article by the Chongqing Iron and Steel Company: Expand Decision-Making Power of Class II Factories and Mines and Mobilize the Enthusiasm of the Basic-Level Units"]

[Text] Our company is a medium-sized integrated enterprise with 23 subordinate factories and mines. Formerly II had two forms of management: seven factories and mines located far from the company practiced a system of internal independent business accounting. Sixteen Class II factories located within the company practiced unified business accounting under the jurisdiction of the company. Production, supply, marketing, manpower, finances and materials of these units were put under the unified management of the company. The company assumed full responsibilities for their profits and losses. The quality of their business undertakings was not linked to the economic interests of the factories concerned, and the practice of everyone "eating from the same big pot" was mainly exercised.

After the experiment of expanding, the decision-making power of the company in 1979, in order to change the situation in which everyone "ate from the same big pot" and fully mobilizes the two kinds of enthusiasm of the company and factories and mines, we worked out an 18-point plan for expanding the decision-making power of the Class II factories and mines. After the experiment, summing up and revision, this 18-point plan was carried out comprehensively in 23 production units on a trial basis. We further expanded the decision-making power of the Class II factories and mines in 1980 and expanded the scope of experiments to the departments and offices of some organs and worked out a 23-point plan for expanding the decision-making power of the Class II units, thus enabling these units to have a certain degree of power to make their own decisions and bring their enthusiasm into fuller play. In our practical work, we have done three things:

We Have Reformed the System of Financial Management and Carried out Internal Verification

We turned 16 Class II factories in Dadukuo district into units which fully practiced independent business accounting and took responsibilities for their own profits and losses in 1979. They opened independent accounts in the People's Bank and established internal accounts in the financial department of the company for the internal transfer of funds. The company handed down separate targets for profit verification to the Class II factories and mines in light of the plans for increasing production and practicing economy. According to the different conditions of various units, the company worked out a provision that the proportion of profit-sharing which was in excess of the plan should be 5 to 20 percent, and the various factories and mines could draw on these reserve profits four times a year for bonuses and public welfare.

The provincial party committee and people's government implemented system of dividing up total revenues between the provincial government and the company in 1980. We respectively changed the company's former system of profit deductions in excess of the plan into the system of dividing up total revenues between the company and the factories and mines and the system of retaining a fixed portion of the profits coupled with that of sharing profits in excess of the plan. The comprehensive rewards for production and the welfare funds for the staff and workers, which were formerly included in production costs, were brought into line with the profit-sharing. As a result, the level of the profits earned by various factories and mines was linked not only with bonuses but also with the welfare funds for the staff and workers. The close integration of power and interests further aroused the enthusiasm of the Class II factories and mines. A heavy rolling mill which uses scrap steel plates as raw materials started to rebuild on its own initiative a mill to produce which were in short supply, thus increasing the variety of designs making an annual profit of more than 500,000 yuan. An ironworks suffered a loss of 5.7 million yuan in its 1980 plan. After practicing the system of sharing total revenues at fixed ratios (few losses means increased profits), the leadership of the ironworks personally explained to the staff and workers the relationships of material interests among the state, the company, the factory and the staff and workers, and adopted a series of effective measures to turn deficits into profits, with the result that new levels of production, quality, consumption and costs were created. Between January and September 1980, the ironworks not only turned deficits into profits but also earned a profit of 2.14 million yuan. We handed down to the staff and workers' hospital and the research institute for occupation diseases the targets for assuming responsibilities for their own expenses, stipulating that their expenses in excess of the plan would not be compensated while surpluses could be retained for their own use. Under the condition that they fulfill the tasks assigned by the company, the institutions such as the designing office, plan control office and research institute for iron and steel were allowed to undertake tasks from other units outside the company and were permitted to retain a portion of the net profits from the revenues they earned. After implementing these practices, the establishments under the jurisdiction of the company carried out service work with units outside the company in an active way and on their own initiative and brought additional revenues to the company.

We Have Readjusted the Prices for Settling Accounts Within the Company and Gradually Solved the Problem of Unfairness in the Division and Allocation of Profits

In the integrated enterprises, among the mines, ironworks, steelworks and rolling mills, due to irrational product prices, a great disparity in profits and losses and unfairness in the division and allocation of profits have long existed. In the past one was concerned about "eating from the same big pot." After the systems of independent business accounting and taking responsibility for one's own profits and losses were implemented the company, the abovementioned problem was strikingly exposed. In order to carry out profit verification and rational redistribution of profits within the company, beginning this year, we comprehensively readjusted and revised the company-wide prices for settling accounts for finished products, semifinished products and labor, fixed prices according to quality and initially solved the problem of unfairness in the division and allocation of profits. The production of steel internally was increased while the importation of semifinished products from other localities was reduced. The production of converter steel should have been an important factor in yielding profits but because of the irrational price set for it the more converter steel produced the greater the losses which dampened the enthusiasm of the converter mill for increasing production. We rationally readjusted the price for converter steel. The output of converter steel doubled and redoubled as a result. In the past, in smelting pig iron in open-hearth furnaces, the ironworks produced more type P 10 iron containing much silicon but less type P 08 iron containing less silicon, thus increasing the difficulty of smelting steel. We worked out a provision that the selling price for every ton of P 08 pig iron should be 5 yuan more than that of type P 10 iron. This helped the ironworks increase the ratio of producing type P 08 pig iron month by month, thus greatly shortening the time period for smelting steel. In the past we produced 10,000 tons of iron mixed with molten iron in a year. The processing unit was not willing to process it while the units which could have used it were unwilling to do. Repeated administrative measures failed to produce any effects; thus it was piling up increasingly. We set rational prices for processing and utilizing iron mixed with molten iron and raised the profit rate in 1980, resulting in an overall increase of profits.

We Have Expanded Decisionmaking Power of the Class II Factories and Mines in the Areas of Manpower, Finances and Materials and Fully Mobilized Their Enthusiasm

The rules for further expanding decisionmaking power provided that the Class II units should have the power to set up any organs concerning personnel matters and matters of labor and capital. They should not be forcibly asked by the departments and offices concerned to suit a particular upper-level department or lower-level unit, under the condition that people be assigned to take responsibility for various kinds of work. They should have the power to appoint and remove cadres at or below the section level in line with the authorized number of personnel handed down by the company. They should have the power to make decisions on giving rewards or penalties to any cadres at or below the section level or any workers (dismissal requires the examination and approval of the company). The power to examine and approve the retirement and resignation of cadres at or below the section level or workers; the power to transfer the workers or to exchange personnel among the various units inside the company. With regard to finances, they should have the power to distribute the funds accumulated through profit-sharing as bonuses or use them to establish collective welfare undertakings and work out regulations for rewards; the power to dispose of their expenses as they wish, use the circulating funds and various other funds allocated by the company, and power for various factoreis and mines to draw on and use funds for overhauling. As for the power to handle materials, they should be in a position to purchase the products which are not subject to unified purchase and marketing by the state; handle the surplus materials which are under the unified arrangements of the company, and moreover, carry out economic coopration with other units and with each other in exchanging surplus materials for materials in short supply. The various rolling mills were allowed to market scrap and substandard rolled steel. At the same time, the Class II units were permitted to undertake processing with locally supplied materials, and imported materials and to contract out other tasks. They were allowed to share the profits earned when they fulfilled the plans for increasing production and for practicing economy designated by the company. Since enjoying these powers, the Class II units have shown greater initiative and flexibility in production and management, brought their enthusiasm into fuller play and given production a great boost under the unified management and guidance of the company.

YUNNAN ATTEMPTING TO CORRECT BACKDOOR DEALING IN CIGARETTES

Beijing ZHONGGUO CAIMAO BAO in Chinese 9 Jun 81 p 1

[Article by Staff writer entitled: "Central Commission for Inspecting Discipline Issues Report on the Large Quantity of Cigarets in Yunnan Used to Secure Advantages and Seeks to Correct the Various Erroneous Actions which Violate Economic Policy"]

[Text] The Central Commission for Inspecting Discipline organized an investigative team to investigate the problem of large quantities of cigarettes in Yunnan used to secure advantages through influence, as reflected by reporters from this paper. The results of the study show that the conditions as reported by our reporters were basically true. For this reason, the commission recently issued a report asking that all levels of leading cadres, particularly responsible cadres in the responsible departments of the party, emphasize the interests of the nation; consider completion of the state plan and acting in accordance with state regulations to be their sacred duty; set an example by resolutely checking the unhealthy tendencies in commercial sales; and correct those erroneous actions which violate the party's relevant economic policies.

Since last year, some leading cadres in Yunnan, out of consideration for feelings, have given large quantities of wholesale cigarettes outside of the supply plan to various personnel and households. This incorrect conduct sets a bad example for subordinates. If it is condoned by the province, it will be condoned by the company and also by the cigarette factory. According to statistics, from January of 1980 to January of this year, due to the pulling of strings in all areas, more than 580,000 cigarettes were squeezed out of the provincial sugar, cigarette and wine companies.

The leading organizations and individuals in some other provinces, cities, and units also take advantage of various connections to put forth all kinds of "needs," ruining the state's product allocation plan, and make purchases of large batches of cigarettes from Yunnan. From January last year through January of this year, there were more than 70 units nationwide which depended on private connections to make large purchases of cigarettes from Yunnan.

Due to the fairly large portion of Yunnan cigarettes which could not get to the market through normal channels, in the short time since last winter, grade A and B brand name cigarettes have vanished over the past 4 months in cigarette-rich Yunnan and in the markets of Kunming. Everyone is talking about it, which has bad effects.

At present, Yunnan Province is in the midst of investigating and rectifying this unhealthy tendency. It has already decided that in the future, no one will be allowed to pull strings in production or sales units seeking cigarettes. At the same time, the various cigarette production, allocation, and sales systems will be researched, established and completed so as to put a stop to the occurence of similar incidents.

The central commission's report points out that cigarettes are allocated by commercial entities in accordance with the state plan. The practice of an individual pulling strings to make purchases of items in short supply outside the plan and not through commercial channels is an unhealthy tendency in the realm of economics. It interferes with normal activity in the market, destroys economic order, corrupts cadres, and encourages the development of the unhealthy tendencies of using connections and backdoor methods. Some elements which are still engaging in speculation and profiteering are causing great harm to the party's prestige with the masses.

The report further points out that this utilization of state materials, making contacts, and using backdoor methods harms the overall interests and allows the unhealthy tendency of individuals or localities obtaining exceptional advantages. These problems occur not only in Yunnan, not only in the cigarette industry, but commonly exist in all localities and all businesses. Some people, in the interest of themselves or a small group, use materials in short supply and the rights of people to establish various kinds of special relationships between people and departments in the name of "cooperation," when in truth it is in search of personal gain. It is through these methods that some individuals make a profit and some units can also gain a definite advantage. However, the existence and expansion of these special relationships cause damage to the state plan, and have an effect on the supply of materials to the masses, and the broad masses are extremely dissatisfied with this situation.

The central commission report asks that discipline inspection organizations at all levels cooperate with the relevant departments and earnestly implement the following:

1. Those units where the conditions of using powers of office and state materials controlled to open back doors and rely on relationships are relatively serious should all take the lead in seriously checking against the "Standards of Political Activity Within the Party" and in the spirit of relevant policies, absorbing the lessons and making thorough rectification.

2. Attention should be given to the manner in which commercial and materials departments implement policies and supply/marketing plans, in order to strengthen controls, tighten systems, plug loopholes, and resolutely check the unhealthy tendency to rely solely on connections to handle matters and ignore state plans. Those party cadres who use their control of materials to bribe or take bribes, engage in graft, embezzlement, speculation, profiteering and other such plots which violate the law should be dealt with severely.

3. The problem of large amounts of Yunnan cigarettes being used for backdoor activities shows that some Communist Party members with responsibilities for leadership work still maintain the notion of special privileges which are not constrained by party discipline or state laws. Discipline inspection departments at all levels of the party should relate the actual situations to those portions of the "standards" which oppose special privileges, educate party members and cadres, and straighten out the thinking to improve the party and to tighten relations between the party and the masses.

DREDGED CANALS ALLOW GOODS DELIVERIES TO REMOTE MARKETS

Beijing ZHONGGUO CAIMAO BAO in Chinese 28 May 81 p 1

[Article by Liang Mingwang [2733 0682 2598] entitled: "The Urgent Need for Small Commodities in Remote Villages]

[Text] Henan has adopted various measures to dredge the canals in order to send a steady stream of many different small commodities used daily to the masses in the mountains and remote areas. The small commodity market throughout the province is a scene of prosperous, brisk activity.

After the implementation of rural economic policies, purchasing power everywhere improved. The rural demand for small commodities used daily is constantly increasing. The demand for product variety is also growing. However, due to the weakness of county wholesale departments and rural businesses at the grassroots level in the management of small articles of daily use, the canals were not clear enough and could not satisfy the needs of the people. In order to change this situation, the department stores of the province, on the basis of common understanding, adopted the following measures:

1. The implementation of specialized management. The vast majority of the province's department stores in the county markets established wholesale departments, turning their emphasis to the villages and making efforts to organize markets to satisfy the need for small commodities. At present, the products handled by small commodities wholesale departments generally number over 1,000.

2. The active expansion of collective businesses, appropriate expansion of individual businesses, and the restoration and expansion of a commercial network. Incomplete statistics from 98 counties and municipalities, after consolidation, register over 27,000 individual general merchandise peddlers who have been issued documents. The mobility of these individual peddlers is great and they play a role in filling in the gaps.

3. Implementaion of the idea of wholesaling for retail service, improving management styles, and making well-stocked collective shops and individual peddlers convenient to grassroots level communes in order to achieve the result of stocking goods so as to avoid delays and a wholesale point allowing for selection, receipt, payment, and delivery of the goods all at once.

After the canals were dredged the markets were revitalized. The total sales amount for small articles of daily use throughout the province last year was almost 21 million yuan. Commercial networks were scattered among all the remote villages. The residents of rural areas can purchase small articles for their own use at any time.

The Qiong Lai [6713 1503] County department store on its own established a small articles management department. Last year's sales of small articles to rural villages totalled over 1.56 million yuan, an average of 4.34 yuan per person.

The sales potential of small articles in rural villages is very great. In order to maintain supplies, the department store established a full-time resident small articles purchasing agent within the countv, increased the fully stocked locations from 4 to 113, and increased the product variety from 4,962 to 6,113 products. Collective businesses were also actively supported and full play was given to cooperatives, promoting dispersed felxibility, making things convenient for the masses, and expanding sales. Last year the sales for collective businesses totaled more than 410,000 yuan, a two-fold increase over the previous year.

INCREASING HANDLING CAPACITY OF FUJIAN HARBORS URGED

Fuzhou FUJIAN RIBAO 28 May 81 p 1

[Article by Yang Baosheng [2799 1405 3932], a staff reporter, entitled: "Provincial Seamen Make Seven Proposals to Tap the Handling Potential of Our Harbors"]

[Text] At the recently convened first labor representatives conference of the provincial navigation bureau, the seamen representatives made some enthusiastic proposals to tap the handling potential of Fujian's harbors. They believe that if these proposals can be implemented, the handling capacity of the harbors will increase approximately 50 percent, maybe even double. The proposals were:

1. Expand work areas. Mawei, Taijiang, Xiamen, Quanzhou, Saiqi, Hanjiang, and other existing harbors in our province are all limited in work area and in capacity. There are many different methods which can be adopted to expand the work areas. For instance, Fuzhou's Taijiang harbor has 5 kilometers of quay from Pier 3 to Kuiqi [7608 1477], with more than 10 work areas which could be selected on the two quays, but at present there are only 6 or 7 work areas. The annual handling capacity has remained at approximately 800,000 tons for a long time, and the docks are pitiful. Futhermore, the anchored pontoon method could be completely adopted in the harbors of Mawei, Xiamen, Quanzhou, and others. For example, in Mawei harbor, if anchored pontoons were used at the anchorage in front of the camp and in the 1,200 meters of water between the large and small reefs below the camp, then 10 to 15 pontoons could be placed, almost doubling freighter work areas. If the work areas were further expanded to Tingjiang [0080 3068] and even Guantou [3828 7333], the handling capacity would be even greater. More than 90 percent of the shipping in Hong Kong relies on pontoon operations. Of course, before the pontoons are anchored, there should first be a survey of the harbor basin structure, water depth, etc., and places where there is no change in the riverbed or where the changes are not great should be selected for anchoring the pontoons.

2. Comprehensively utilize the docks. Dock operations are, in the final analysis, superior to mid-river flat barge operations and the docks should be fully utilized by every possible means. At present, in addition to the dredging of dockside basins which have become shallow through silting, comprehensive utilization of the docks should be improved. At Mawei harbor, for instance, reasonable arrangements should be made to use the Port Affairs Bureau dock, and the docks of the departments of foreign trade and marine products should be put to integrated use. An integrated plan, integrated management, and integrated usage should be implemented to give the

greatest role possible to each dock in striving to service the ships. In the utilization of speciality docks, we should reasonably comply with the definite expenses of the departments concerned and not engage in the "indiscriminate transfer of resources."

3. Increase the number of lighters. When there are an insufficient number of docks and mid-river operations are undertaken, lighters are an important tool. The number of lighters in our existing harbors is in general insufficient. For instance, in Mawei and Taijiang harbors there are only 60 some special lighters, nearly 8,000 tons, but with normal repairs, etc, only about 6,000 tons can be in actual operation. When such large ships as the "Daiyunshan" [2071 0061 1472] and the "Baiyunshan" [4101 0061 1472] are in port, 40 lighters are occupied at one time over a period of more than 10 days. This being so, the other vessels in the harbor can only sit empty, waiting. The harbor of Quanzhou has only 640 tons in special lighters, leaving practically no way to handle the vessels coming to the harbor to load or unload. If this condition of insufficient lighters is not alleviated there will be even less chance to improve the handling capacity of the ports. Using lighters also requires a certain number of tugboats. At the same time, different lighters must be devised for different harbors. Consider for instance the water depth in Xiamen harbor. The use of a certain number of large lighters with deep holds, the study of foreign experiences, and the installation of cranes on the lighters can be considered in order to improve the loading and unloading capacity of lighter operations.

4. Increase the number of stevedores. A sufficient number of stevedores is essential to insure quick loading and unloading in a harbor. This is especially so in the slightly mechanized harbors of Fujian, and an appropriate increase in the number of stevedores is necessary. Currently, the condition of insufficient stevedores in our province is fairly obvious. In Mawei harbor, for instance, there are only 500 stevedores, divided into 41 crews. In addition to dock operations, there are only about 30 crews sent out daily for shipboard operations. On the basis of three shifts for continuous 24-hour operations, there can only be an average of 10 crews per shift, which can only work two or three ships. For this reason it is best to solve the problem using the "scratch the surface," or reduced open hold and suspended operations methods, affecting the loading/unloading schedule. The adoption of a combined method of fixed wages and commune or brigade contract work can be considered to increase the number of stevedores in the future, that is, instituting more collectively owned labor, which also allows for a ship's crew to load and unload their own vessel. The stevedores should institute piecework wages which would allow them slightly better pay than other types of labor and would promote and improve the rate of work. The harbors should increase the education and control of stevedores, improving their ideological and political level and their professional and technical skills. Those harbors without night operations should improve conditions, overcome bad habits, and implement night operations.

5. Expand warehousing in the port districts. At present, warehouses and stockyards in our harbors are in short supply and there is no place to stockpile cargoes. Programs and appropriate expansions should be quickly implemented. The construction of simple warehouses and other such methods can be adopted to solve the problem. The establishment of local administrative departments should be set forth by the bureau to make harbor navigation more convenient and to support harbor traffic. The "control, check, and suppress" method, the use of limits, rents or fines, and other such procedures should not be adopted to constrain the expansion of harbor traffic, creating undeserved losses for the state.

6. Implement a system of economic responsibility. In port operations, the harbor, ships, and the cargo are all closely related. If one link comes apart it affects the whole situation. According to statistics from the Fuzhou Harbor Bureau, during the first quarter of this year, 41 percent of the time a ship spent anchored in Mawei harbor was nonproductive. No labor and no lighters available in the harbor accounted for 48 percent, ship repairs for 11 percent, and cargo nonavailability accounted for 39 percent, and other reasons accounted for the remaining 2 percent. The importance of the relationship of the harbor, ships, and cargo can be seen. At present, there is nothing binding the harbor, ships, and cargo; whichever sector is affected can only complain and argue. There is no economic responsibility. In the future, a system of economic responsibility should be established in order to make shipping guarantee transport, the harbors guarantee loading and unloading times, and the cargo sector guarantee the supply or acceptance of a specified quantity of goods within a specified time period. Whichever sector causes a delay will hold economic responsibility and the responsibility for restitution. At the same time, work should be done to improve the shipping and connections with trains, trucks and other short-haul transportation modes.

7. Reform the system of control. Ships and ports are two facets of a whole. They are interdependent and inseparable. If harbors lack ships then service is lost, if ships lack harbors there is no way to carry out production. For this reason, it is proposed that some of our existing harbor systems be reformed. For instance, over 80 percent of the work in Mawei, Xiamen, Quanzhou, Saiqi, and other harbors is to service the loading and unloading of the ships or our province, but since the division of shipping and port affairs in 1975, each sector does things its own way, even though both are under the guidance of the transportation office, and for this reason there are disputes alternating between the organizations and the tax office. If this can be reformed, then the existing matter of preferring to guarantee smalls sums over large sums (i.e., the port is the guarantor for losses to lighters, so they prefer handling large vessels because when large ships are in the harbor, although their losses are 6,000 or 7,000 per day yuan, those losses are the shippers', and although, the losses for the lighters are small, they must be borne by the port) can be avoided and at the same time be beneficial to the command and control of ships. After the port and shipping sectors are combined, the establishment of harbor affairs bureaus in Mawei and Xiamen can be considered. From the provincial maritime leadership, through strengthening the leadership control of these two major ports, to the harbor systems of other small harbors such as Quanzhou, Saiqi, Hanjiang, and others--all can be completely restored to the conditions prior to 1975.

The seamen representatives said that many of their proposals were ones which had been thought of long ago, and the key now is to do those things to correct the situation. However, due to the diverse aspects involved in harbor operations, the problem cannot be solved by the Ministry of Transportation alone. Therefore, it must also be embraced by first-level units in the province and closely coordinated by the relevant local (municipal) and county entities. Only if we earnestly and thoroughly implement the spirit of the Party's Third Plenary Session, be wholeheartedly dedicated, immerse ourselves in hard work, and relieve our present harbor traffic jam can the "bottleneck" be solved.

FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

[Text]

Abstract

In this paper the problem of total population target in China has been investigated and discussed. More than 20 factors affecting the total population after 100 years have been analyzed from the trends of development and the viewpoints of natural resources, environments, economics, state of population, psychology of all nationalities, etc. System's engineering's multiobjective decision-making techniques have been used to try to treat the dynamic relations among these interactive factors. The optimal target of 0.7 billion is obtained from our investigation. If the results of our efforts are better than our estimations, or if the standard of living of the people is lowered, the optimal population can be increased from 0.7 to 1 billion.

Foreword

What is suitable for "human" habitation at present is our earth. This sets limits to the population of mankind. The whole earth has a surface area of 510 million square kilometers including land area of 148.9 million square kilometers and ocean area of 361.1 million square kilometers. The natural growth rate of world population is 1.8 percent at present. Estimated on the basis of 1 square meter per capita, human beings will fill the land area in 585 years and spread to the whole globe in 653 years--mountains, lakes, plains, deserts, forests, and oceans.

Today, human activity has reached such an extent as to affect nature and the earth itself. This fact poses a question for mankind: Are "the growth in the population of mankind and the improvement in living quality" compatible with "the growth in human capacity" and in harmony with "the environment on which mankind depends for survival?" This question involves social problems of the whole world and each sphere of human activities. Even if it is confined to one country, the factors involved are so numerous and the relationships are so complex that it is difficult to make a generalized study. In this paper, an attempt is made to use the technique of multiobjective decision-making in systems engineering to probe into this question. First, we separate the inter-connections among various factors and separately study the partial effects of individual factors and then sum up their total effects, giving consideration to the interconnections among the various factors.

Through theoretical analysis and estimates, the major cycle of population growth in our country is estimated at about 70 years, which is close to the average lifespan of man. Therefore, in approaching the problem of population control in our country, we should go beyond 70 years to consider policy measures to be taken today. Thus, in this paper we take 100 years as the time range of discussion. This will take account of the tremendous inertia of population process and the possibility of forecast while leaving room for approximate change in the development of things and the policy decision.

Opinions vary over the problem of total population target. Some say 200 million is just right. Others say 300-400 million is proper. Others say 500-700 million is optimal. Still others say 800 million to 1.5-2 billion is also feasible. This shows people are universally interested in this problem. In this paper we join in the discussion and offer our views; more importantly, we apply systems engineering methodology and offer a scientific policy-making method.

We approached the problem from 20 angles, then combined them into nine categories, and finally summed them up as "possible and satisfactory" extent of total population, which is used to reflect the rationality of the total population target in relation to "needs and possibilities," thereby providing a basis for determining the total population target.

1. Land Potential

Our country has 9.6 million square kilometers of land, equivalent to 14.4 billion mu. As things stand at present, there are 1.5-2 billion mu (10-14 percent) of cultivated land, 1.83 billion mu (12.7 percent) of forests, 4-5 billion mu (28-37 percent) of grassland, more than 4 billion mu (27 percent) of wasteland and barren hills, 300-400 million mu (2-3 percent) of fresh water surface, and more than 2.2 billion mu (15.9 percent) of barren soil like deserts and gobi.

Forests play a very important part in regulating the climate and weather and in conserving water and soil. The rates of world forest cover are 22-28 percent, 34 percent for the U.S., 40 percent for the Soviet Union, and 29 percent for Europe. According to estimation by experts in the fields of agriculture, forestry, and ecology, the optimal rate of forest cover is around 30 percent. As far as our country is concerned, forest cover should reach 4.3 billion mu. Within this context, a forest cover rate of 30 percent and more may be considered fully satisfactory. Thus, we take the "satisfactory extent" -- Q_1 ($\geqslant 30\%$) = 1.0. The present rate of 12.7 percent is extremely unsatisfactory; we take Q_1 ($\leqslant 13\%$) = 0. The satisfactory extents between 13 percent and 30 percent cover rates are connected with a straight line as indiciated by diagram 1(a).

At the present stage, more than 60 million mu are afforested each year. If the annual afforestation decreases progressively (with afforestation becoming more difficult as time goes on), in 50 years afforestation will increase by 1.5 billion mu, and in another 50 years the forests will be stabilized, bringing the total forest area to 3.33 billion mu and the cover rate to 23 percent. We take the possibility -- P_1 ($\leqslant$ 23%) = 1. By afforesting 70 percent of barren hills and wasteland and 30 percent of deserts and barren soil, the cover rate can be brought to 37 percent. We take the possibility -- P_1 ($\geqslant$37%) = 0. The curve is as indicated by figure 1(a).

As to cultivated land, the average around the world is now 10.8 percent; 10.8 percent for the Soviet Union, 22.4 percent for the U.S., and 14.3 percent for Japan. In our country, the reclaimable wasteland is estimated at 1.5 billion mu. This plus 2 billion mu of existing cultivated land may bring the total rate to 24 percent. But there are people who estimate that there is not much wasteland that can be reclaimed and that expansion of forests will affect land reclamation. Now we take the possible extent -- P_2 ($\geqslant$ 24%) = 0, and take P_2 ($\leqslant$ 14%) = 1. The possible extents between 14-24 percent rates of cultivated land are connected with a straight line as indicated by figure 1(b).

2. Water Potential

Our country has 2.7 trillion tons/year of surface water (river runoff) and 1 trillion tons/year of shallow groundwater. These sources of water are replenished by rainwater. In terms of the present water per capita, they are up to only one third the world level (not counting groundwater). The total volume of water used for industrial and agricultural purposes in 1979 accounted for about 18 percent of surface water.

In the United States, annual river runoff amounts to 2.4 trillion tons/year, of which 25 percent had been developed as of 1975, and it is estimated that 40 percent will be developed by the year 2000. Japan has 200 billion tons of surface water and as of the seventies was utilizing 45 percent.

We take the possibility of 50 percent utilization of surface water in our country after 100 years--P_3 ($\leqslant$ 50%) = 1, and take the possibility of 100 percent utilization--P_3 ($\geqslant$100%) = 0.

As for groundwater, we leave it out of account because it is not possible to take groundwater as an independent water source. Besides, over-exploitation will cause earth subsidence.

70.8 percent of the earth's surface is oceans, and sea water accounts for 97.2 percent of the total volume of water on the earth--1.3-1.4 billion cubic kilometers. Ice accounts for 2.16 percent, and fresh water 0.64 percent. Thus a huge volume of water is in the oceans. Desalination of sea water consumes enormous amount of capital and energy and we should not place great hope on it at present.

The situation being what it is in various countries of the world, what should be particularly guarded against at present is the pollution of water sources. Our country should pay full attention to this problem and prevent water pollution in the next hundred years. So the curve for the potential of utilizable water is indicated by 1(c).

3. Air Potential

Man is breathing at all times and all animals breathe. They keep inhaling oxygen and exhaling carbon dioxide. Mineral fuels consume enormous volumes of oxygen when burning and generate carbon dioxide.

The supply of oxygen is attributable to photosynthesis of plants. There are 26 billion tons of plants on the land of the earth and 18 billion tons of green planktons in the oceans, consuming 1.6 trillion tons of carbon dioxide and generating 1.2 trillion tons of oxygen.

The percentage of carbon dioxide in the atmosphere is increasing at present. Whether this phenomenon is good or bad has not been determined. Some scientists are of the opinion that the greenhouse effect caused by the increase of carbon dioxide will increase the average temperature on the earth and cause the polar icecaps to melt, submerging vast tracts of land. Others take the view that pollution of the atmosphere and the increase in powder and dust will decrease the quantity of heat of sunlight on the earth, thereby bringing about a new ice age. According to an agriculture science station in the United States, at the present level a one percent increase in carbon dioxide will accelerate photosynthesis 0.5 percent and lend itself to a bumper harvest in agriculture. It has been reported that bumper harvests were gathered in the vicinity of carbon dioxide wells in some parts of our country.

Thus, it is not known what the ideal density of carbon dioxide in the atmosphere is. However, it may be preliminarily affirmed that changes of carbon dioxide and oxygen should approach a balance after 100 years.

Since the atmosphere is a global phenomenon, it has no national boundaries. However, regional effects caused by uneven regional distribution are still existent.

In our country, on the basis of 4.3 billion mu of forests, 5 billion mu of grasslands, and 3.5 billion mu of farm crops, the total capacity for absorbing carbon dioxide is estimated at about 95 billion tons/year. We take the possibility of achieving this as 0, and the possibility of a 35 billion tons/year CO_2 absorption rate with present forests/cultivated land as being 1. The corresponding curves are shown in diagram 1(d).

The ratio of capacity for generating oxygen and that for absorbing carbon dioxide is about 32:44. Thus, there is no need to take carbon dioxide into separate consideration. As for other harmful air pollution, where pollutants cannot be absorbed by green plants, additional measures should be taken to solve the problem.

4. Energy Potential

All activities of mankind are inseparable from energy. Our country is comparatively rich in energy resources. Verified coal reserves have reached 641.8 billion tons, petroleum 2.74 billion tons, and natural gas 700 billion cubic meters. Among the regenerated energy resources, there are about 680 million kilowatts of waterpower, and 1-2.5 billion kilowatts of solar energy. In addition, geothermal, tidal energy and wind energy have exploitable potential, but relatively speaking this is not great On the other hand, atomic energy and nuclear-fusion have exceedingly great potential.

Taking the country as a whole, in the near future we should fully utilize mineral fuels, particularly coal. Taking a long-range view, we should vigorously develop new energy resources like solar energy and atomic energy. In this way, if all the water energy and solar energy that can be technically and economically opened up are put to use after one hundred years, the total volume of energy will be equivalent to 870 million-1.37 billion tons of standard coal/year. Further, assuming that atomic energy and other new energy resources fully supplant all the energy resources we have at present, there will be energy resources equivalent to 2 billion tons of standard coal/year. After 100 years, this level will be reached if the 1979 energy production level is increased at a progressive rate of 1.175 percent a year.

The annual rate of energy growth was 3.4 percent in the U.S. during 1950-1973. According to estimates by the International Energy Organization, the annual rates of energy growth in the U.S. will be 3.7 percent in 1976-1985, 2.9 percent in 1985-1990, and 2.2 percent in 1990-2000. Corresponding growth rates will be 5.9 percent, 5 percent, and 4 percent in Japan; 2.7 percent, 2.1 percent, and 2.2 percent in the United Kingdom; and 4.9 percent, 4.1 percent and 4.1 percent in France.

During the periods of "first 5-year plan," "second 5-year plan," three-year adjustment, "third 5-year plan," and "fourth 5-year plan," annual rates of energy growth in our country were respectively 18.6 percent, 11.4 percent, 4.5 percent, 9.1 percent, and 7.9 percent. The average rate of annual growth was 10.7 percent during 1953-1978.

In all, the likelihood of an average 2 percent energy growth in 100 years from now on may be taken as 1, and the possibility of a 5 percent annual growth rate may be taken as 0. The curves are indicated by 1(c).

5. Potential in Per Mu Output of Grain

Average output per mu in our country was 137 jin/mu.year during 1949, 332.1-442 jin/mu.year (calculated on the basis of 2 billion or 1.5 billion mu) during 1979. The average annual growth rate was 3.00-3.99 percent. As to world average level of output per mu during 1979, it was 740 jin/mu.year in Japan, 591 jin/mu.year in France, 486 jin/mu.year in the United States, and 528 jin/mu.year in Denmark. During 1949-1979, the average amount of annual grain increase was 6.5-10.2 jin/mu.year in our country. Calculated by arithmetical progression, in 100 years per-mu output will also increase to 982.1-1,461.8 jin/mu.year, and the average annual growth rate will be 0.8 percent-1.1 percent.

In light of the world level mentioned above, we take the possibility of 500 kilograms per mu p6 (≤ 500) = 1. And the possibility of 1,500 kilograms and more p6 (≥ 1500) = 0. The curves are indicated by figure 1(f).

6. Aquatic Production Potential

World catches were 21 million tons during 1950, and reached 69.70 million tons during 1975, with an annual growth rate of 4.9 percent. In addition, worldwide breeding of aquatic products is expected to reach 70 million tons by the year 2000, topping the total volume of the present worldwide catches.

In Japan, where coastal waters are utilized, the area of unit output of fish has reached 5.3 tons/hectare. Our country has 13.5 million mu of shallow coastal waters and 24 million hectares of coastal waters equivalent to domestic shallow water surface. Estimated even on the basis of unit output of 1 ton/hectare, output is expected to reach 24-48 million tons/year.

If estimated according to bait, world fish output may increase by 10-100 times. At a certain ratio our country may have a share amounting to 45.5 to 455 million tons/year.

China's total output of aquatic products was 4.305 million tons during 1979. In light of the above state of affairs, we take the possibility of reaching 20 million tons/year in 100 years, p7 (≤ 0.2) = 1, and take the possibility of reaching 150 million tons/year, p7 (≥ 1.5) = 0. The curves are indicated by 1(g).

7. Economic Development Potential

Except for the 7 items mentioned above which are limited by resources, the various necessities of human life--food, clothing, shelter, and transportation--may be incorporated into the economic development potential and considered in these terms.

GNP is an index of the relative strength of the national economy. GNP may approximately demonstrate the consumption scope in a country.

The ratio of energy growth rate to the rate of gross industrial output is called energy elastic coefficient. Our energy elastic coefficient was 0.95-1.0 during 1950-1978. On the whole, the trend of development of elastic energy coefficients in various countries is on a gradual decline. For example, it was 0.94 in the U.S. during 1950-1973. It is estimated that it will decline to 0.6-0.7 by 1978-1985 and to 0.55-0.65 during 1985-2000. The trend is particularly evident in energy-deficient Japan: it was 1.0 during 1960-1979 and declined to 0.43 during 1975-1978.

Therefore, as far as our country is concerned, along with the spread of energy conservation techniques it can be predicted that in 100 years the energy elastic coefficient will gradually decline to at least 0.5. Thus, on the basis of the possible extent of an annual energy growth rate as indicated by diagram 5 of curves, we can work out the curve of the possible annual growth rate of the GNP. Take 3 percent and 7.5 percent as the turning points, and we get what is indicated by figure 1(h).

8. Per Capita Food Requirements

Man's nourishment is very rich in content, but the most principal and representative indicators are calories and proteins. The World Health Organization has set one standard: 3,000 large calories/person.day for an adult male and 2,800 large calories/person.day for an adult female. The former standard set by our country is close to that while the standard set in the United Kingdom is said to be 2,470-2,567 large calories/person.day. As for protein, the United Nations has proposed 70 grams/person.day, of which 40 percent should be animal protein. China formerly had a standard of 80 grams/person.day. Therefore, we may adopt 2,500 large calories/person.day and 80 grams of proteins/person.day. Animal nourishments accounting for 40 percent are taken as standard nourishment converted into food forms: 400 grams of cereals, 100 grams of animal meat, 80 grams of fish, 48 grams of eggs, and oil, sugar and vegetables.

Thus, the standard grain ration is 400 grams/person.day. This plus fodder grain which is about seven times the amount of meat and also industrial grain and loss which double the amount makes a total of about 800 kilograms/person.year. We take the satisfactory extent -- P_9 ($\geqslant 800$) = 1. As to 400 kg/persons.year, which does not include grain for industrial purposes and loss, we take the satisfactory extent--Q_9 (400) = 0. These are indicated by figure 1(b).

9. Per Capita Livestock Requirements

From the above we come to know that animal meat per capita is 100 grams/person.day, which converts into 3.65 kilograms/person.year. Per capita output was 10.8 kilograms/person.year during 1979.

Total production of pork, beef and mutton amounted to 10.624 million tons during 1979. The corresponding number of pigs was 319.705 million head, that of cattle 71.346 million head, that of sheep 183.42 million head. Now, on a pro rata basis we can work out per capita livestock requirements: 1.1 pigs/person, 0.25 cattle/person, 0.63 sheep/person. Reduced to standard livestock of 50 kilograms each, it is about 5.2 standard head/person. We take the satisfactory extent--q10 ($\leqslant 5.2$) = 0, and take the satisfactory extent (with 50 percent as surplus)--q10 ($\geqslant 7.8$) = 1, as indicated by figure 1(f).

10. Per Capita Fish Product Requirements

From item 8 we know fish requirements per capita are 80 grams/person.day. It is estimated that fish good for food make up about 75 percent of catches, and that half of them are waste. It is known that per capita fish product requirements are 78 kilograms/person.year. We take the satisfactory extent, Q_{11} (78) = 1, and half the satisfactory extent, Q_{11} (39) = 0, as indicated by figure 1(g).

11. Per Capita Energy Requirements

Human activities are inseparable from energy. On the basis of 2,500 large calories/person.day required to maintain the life of each person, the requirements are equivalent to 0.13 ton of standard coal/person.year. And to produce foods with so many calories it is necessary to consume more energy to the extent of from 0.013 to 1.56 tons of standard coal/person.year, depending on the kinds of foods produced. In addition, under conditions of modern society, clothing, food, shelter, transportation, culture and recreation require large amounts of energy. On the basis of 3,099.5 large calories/person.day, it is estimated that 1.615 tons of standard coal/person.year are required.

Per capita consumption of energy is the highest in the United States. Per capita consumption of energy was 11.574 standard tons/person.year in 1977. Japan, a country "deficient in energy" pays great attention to energy conservation; per capita consumption of energy during 1977 amounted to 3.806 tons of standard coal/person.year. Actual levels of consumption in the three major cities of Beijing, Shanghai, and Tianjin during 1979 were respectively 2.24, 1.70, and 1.47 tons of standard coal/person.year. On this basis, we select the satisfactory extent of per capita consumption of energy as follows: q12 (4.0) of 4 standard tons/coal.year = 1, and q12 (1.6) of 1.6 tons of standard coal/person.year = 0, as indicated by figure 1(e).

12. Per Capita Water Requirements

Man cannot live without water. With the development of industry and agriculture, water is increasingly showing its value. Per capita consumption of water in the U.S. reached 2,300 tons/person.year during 1965 and increased to 2,880 tons/person.year during 1975. It is estimated that by the year 2000 per capita consumption of water will reach 4,550 tons/person.year. Per capita consumption of water in Japan reached 789 tons/person.year in the mid-seventies.

In our country, consumption of water for industrial, agricultural and living purposes was approximately 400-500 tons/person.year during 1979. We take the satisfactory extent of 2,880 tons/person.year in the U.S. in the mid-seventies, q13 (2,880) = 1, and take the satisfactory of 500 tons/person.year in our country, q13 (500) = 0, as indicated by figure 1(c).

13. Per Capita Air Requirements

An adult needs 1,000 liters of air a day, inhaling 0.75 kilogram of oxygen and exhaling less than 1 kilogram of carbon dioxide equivalent to approximately 0.365 tons/person.year. In addition, per capita livestock requirements are 5.2-7.8 standard head/person. It is not possible to estimate wild animals. For the time being, we estimate them on the basis of the same number of domestic animals.

The ratio of mineral fuels to energy resources after 100 years is estimated at 50 percent at the highest and 5 percent at the lowest. Carbon dioxide thus generated will be about 0.73-7.3 tons/person.year.

Altogether, the amount of carbon dioxide averages about 4.8-13.4 tons/person.year. The oxygen needed may be worked out at a 32:44 ratio. Figure 1(d) is the curve of the satisfactory extent of per capita carbon dioxide.

14. Per Capita GNP Requirements

From discussions in item 8 it may be realized that this indicator can roughly reflect people's living standards. According to figures released by the World Bank, in 1978 per capita GNP was US$12,700/person.year in Kuwait (world's highest); US$9,960/person.year in Switzerland; US$8,640/person.year in the U.S.; US$5,640/person.year in Japan; and US$3,011/person.year in the Soviet Union. The world average was US$1,800/person.year.

Our country's per capita GNP level is now about one sixth the average world level. The highest world level is 47 times ours. Therefore, it is not so satisfactory for us to reach the present world level after 100 years. We should take q15 (1,800) = 0. The curve is indicated by figure 1(h).

15. Per Capita Housing Space and Land Requirements

The per capita housing space is 29 square meters in West Germany, 18 square meters in the U.S., 13 square meters in Japan, and 7.2 square meters in the Soviet Union. Per capita housing space is 3.6 square meters in our country, and some people estimate that by the year 2000 it will reach 10 square meters. We take 30 square meters and 5 square meters as the turning points of the satisfactory extent of per capita housing space. Housing space accounts for about 65 percent of the area of structure. Streets account for approximately 10-30 percent of the urban areas. It is assumed that land for public buildings is offset by the ground area saved from high-rise buildings.

Urban afforestation area is included in forests and grassland. Factories, mines and transportation use large amounts of land. Over the past 30 years they have taken up 150 to 180 million mu of land.

Taking all this into account, we may take the satisfactory extent of per capita use of land, 0.3 mu/person, q16 (0.3) = 1, and the satisfactory extent of 0.18 mu/person, q16 (0.18) = 1 [as published; should be 0] as indicated by figure 1(i).

16. Possibilities of Land Used for Housing, Industry, and Transportation

Forests, cultivated land, barren hills and waste land make up approximately half of the total area of our country at present. If we want forests to take up 37 percent and cultivated land 24 percent in the future, we will have to turn to deserts, gobi and grasslands, and must use the land sparingly. In the 20 years from 1957 to 1977, cultivated land in our country decreased by 180 million mu, or 10 percent. It is assumed that 15 percent and 30 percent are taken as the low and high points in the possibilities of land for housing, industry and transportation. Taking account of the possibilities of cultivated land (see item 2), we can work out the low and high points, 2.1 percent and 7.2 percent of the total area nationwide.

17. The Lowest Total Birth Rate Acceptable to the Masses

The total birth rate (B) is approximately equivalent to the average number of children begotten by a married couple in their lifetime. The number of births was 2.2 in 1979. If childbirths follow the trend of the past few years and drop by 0.1 a year, childbirths are expected to drop to 1.5 by 1986. By that time, in the rural districts, which account for 80 percent of the total population, 40 percent will have one child and 6 percent two children each. In cities, which account for 20 percent of the total population, 90 percent will have one child each and 10 percent two children each. It is predicted that after 100 years the population will be 603-777 million. We take this possibility, $p18\ (\geq 7.0) = 1$. If within 100 years 100 percent of the population will have one child each, it is predicted that the population will be 233-370 million after 100 years. Under the conditions of our country, it is difficult to achieve this. We take the possibility of this, $p18\ (\leq 3) = 0$ as indicated by figure 1(j).

18. Limit to the Ageing Coefficient

The ratio of persons aged 65 and over to the total population is called the ageing coefficient (l_2). Distribution of the ages of the present population being what it is in our country, to lower the level of the total population in 2080 will certainly bring about a growth of l_2. L_2 in the next hundred years. It is necessary to put forward the hopes for limits of l_2.

From analysis we come to know that with present mortality rates, the corresponding base value of L_2 is about 0.14. This being so, we think that as long as L_2 is smaller than or equivalent to 0.15 it is satisfactory, and that L_2 larger than or equivalent to 0.3 is unsatisfactory. Through calculations based on more than 30 schemes, we have worked out the corresponding total population after 100 years to be 1.4 billion and 500 million. Therefore, we take the satisfactory extent, $q19\ (\geq 14) = 1$, and $q19\ (\leq 5) = 0$. The curves are indicated by figure 1(k).

19. Comparison of Total Population with Various Countries

Our country has always been the largest one in terms of population. Total population is one aspect of national strength. Therefore, a direct comparison with various countries should be taken into consideration.

Countries with a population of 100 million or more are China, India, the Soviet Union, the U.S., Indonesia, Brazil, and Japan. In the case of the last four countries, the maximum population does not exceed 360 million. Therefore, what we need to watch is the development of population in the Soviet Union and India.

The Soviet Union is pursuing a policy of population growth. Its present population is 264 million and its natural growth rate is .9 percent. In 100 years constant growth will bring its total population to 647 million. We take its satisfactory extent - $q_{20R}\ (\geq 6.5) = 1$ - and take the satisfactory extent of 450 million (30% less) - $q_{20R}\ (\leq 4.5) = 0$.

India has a population of 667 million and its natural growth rate is 2.1 percent. By the end of this century it will grow to 1.0107 billion. Its maximum population is estimated at 1.6 billion. Therefore, we take its satisfactory extent - q_{201} $(\geqq 10) = 1$ - and take q_{201} $(\leqq 7) = 0$. The above curves are indicated by figure (1).

20. Overview

The above are more than 20 factors considered. Figure 1 indicates the possible extents and satisfactory extents of the various factors. They may be combined by using the technique of multiobjective decision-making techniques in systems engineering. The process of their combination is illustrated by figure 2 with the following results:

1. Viewed from the aspect of grain, the possible-satisfactory extent of total population is 1 when it is less than 1.26 billion, and 0 when it exceeds 6.48 billion.

2. Viewed form the production of fish, the possible-satisfactory extent of total population is 1 when it is less than 260 million; thereafter, it begins to decline slowly.

3. Viewed from the use of land for industrial, transportation and living purposes, the possible-satisfactory extent of total population is 1 when it is less than 1 billion, and will decline to 0 when it exceeds 5.67 billion.

4. Viewed from the use of water, the possible-satisfactory extent is 1 when the total population is less than or equals 450 million, and will drop to 0 when it exceeds 5.4 billion.

5. Viewed from the changes in oxygen and carbon dioxide, the possible-satisfactory extent is 1 when land is rationally distributed and the total population is less than or equals 2.6 billion.

6. Viewed from standpoint of energy, the possible-satisfactory extent is 1 when the total population is less than or equal to 640 million.

7. Viewed from GNP, the possible-satisfactory extent is 1 when the total population is less than or equal to 640 million.

8. Viewed from the process of population development, the possible-satisfactory extent is 1 when it exceeds 1.4 billion and is 0 when it is less than 500 million.

9. Viewed from the comparison of population with other countries, the possible-satisfactory extent is 1 when the total population is larger than 1 billion, and is 0 when it is smaller than 450 million.

Curves of the above possible-satisfactory extents are indicated by diagram 3. If these factors are satisfied fully and simultaneously, the highest possible-satisfactory extent is only 0.25, which is obviously not good enough. Here we can find that water consumption, GNP, and population development process produce the greatest effects. The process of population movement is caused by the present surging distribution of population ages. As a result of estimations and calculations based on "scores of plans," it is discovered that the proportion of old people around 2040 will be too large, making it necessary to make arrangements at an early date. As to use of water, care should be taken to use water rationally and to prevent pollution. As to GNP, efforts must be made to strive for steady, high-rate growth.

From different viewpoints, six plans are listed below (see "Comparative Table of Six Plans for Total Population Target in China"). From the table it may be noted that if we consider only food and things for use and the economic strength, it would be advisable to keep the population target below 540 million; if mutual compensations for certain factors are permitted as indicated by plan 4, then the population target should be kept below 760 million, and its possible-satisfactory extent is above 0.9. However, we cannot but consider the actual conditions of population development, particularly the average number of births by a married couple that is acceptable to the masses of our country. As to the peak of ageing coefficient that will appear in the forties of the next century, we may use our economic strength to tide us over.

Thus, plan 5 is formed with 700 million as its population target and 0.65 as its possible-satisfactory extent. It seems plan 4 is desirable and, if mutual compensation for certain factors is permitted, plan 6 is formed. Here the population target may be raised to 700 million-1 billion.

Diagram 4 indicates the possible-satisfactory extents of the six plans. From the curves we can clearly see that after 100 years from now on 700 million appears to be optimal target of total population and that if things are stretched a bit, the target may be raised to 700 million-1 billion.

We feel that the problem of total population target is one of utmost importance to our country. With this target set, we can find out the best tactics to control the process of population development, and a clear orientation for population control in our country. At the same time, we can know from various conditioning factors which are serious, which are moderate, which should be given double care, which are the focal points of work. This will led itself to the planning and coordination of various kinds of work.

With time, the development of science and technology, the progress of society and the deepening of our knowledge, we may keep determining the total population target to be reached 100 years from now on and aim all policy decisions at this target. In this way, we shall always be in control.

Plans for Comparative Table of Total Population Targets in China

Plans	Factors considered										Total pop. in 2080 (100m)	Possible-satisfactory extent (degree of rationality)

REORGANIZATION OF MACHINEBUILDING INDUSTRY DISCUSSED

HK141530 Beijing JINGJI GUANLI [ECONOMIC MANAGEMENT] in Chinese No 6, 15 Jun 81 pp 7-11

[Article by Wu Ming [0702 2494]: "Reorganizing and Restructuring Our Machine Building Industry"]

[Text] Leading comrades from the Party Central Committee recently pointed out that the machine building industry is closely related to the modernization of the whole national economy. At present it is important to readjust and restructure the machine building industry because this is not only a major aspect of economic readjustment but also the starting point for realizing our modernization plan. They also said that many of the principles for reorganizing and restructuring the machine building industry are applicable to many other industries. These directives are of great significance to the present readjustment of our machine building industry and all of industry and to their future development.

(I)

People are familiar with this thesis of Lenin: "A big machine building industry is the only foundation for socialism." For our country, in order to realize the great cause of the four modernizations we must depend on a machine building industry that is capable of producing machinery with advanced technology and in large enough quantities to establish and restructure various economic departments and step up national defense construction. In carrying out the construction principle with technical innovation as the key, the machine building industry, in particular, will have to shoulder even heavier tasks. After three decades of construction, new China already has a substantial scale of production and technical level. In developing our national economy and the four modernizations we must pay attention to and rely on the existing material and technical foundations so that they will be able to fully play their roles. Our industry must no longer rely on carrying out new and big projects as a way to expand reproduction, nor must we rely on extension to expand reproduction. On the contrary, we must turn to intension as the key and rely on the 40 million workers and staff of the present 370,000 enterprises to improve efficiency of the means of production and create more material wealth through tapping potential, restructuring and strengthening management. In the past we relied on building new projects as the key; but in the future it is necessary to take transforming the existing material and technical foundations as the key because this measure is a strategic principle for building our economy.

People still remember that following the initial establishment of the foundation for industrialization during the first 5-year plan, it was suggested that we resort to the principle of carrying out technical innovations as the key. But this suggestion was basically not carried out even many years later. As a result, much money was spent but with little economic effect. Undoubtedly it is still necessary in the future to carry out new and important projects, but the key task must be to constantly restructure the existing material and technical foundations so as to comprehensively increase economic and technical results. This is a new method never used before in economic construction. Undoubtedly when our socialist construction is advancing along this road, the machine building industry, which is the basic lever in restructuring the national economy, will be able to play a still greater role.

(II)

Will our machine building industry be able to meet the need of the principle which takes technical innovation as the key? Viewing the present situation, it is hard to say; but through hard work in reoganizing and restructuring, it is possible for the machine building industry to meet the need.

Our machine building industry has made great progress over the past three decades and we have formed an industrial system of considerable size, with fairly complete departments and of a considerably high standard. There are tens of thousands of key machine building plants and hundreds of thousands of ordinary machine building plants, coupled with a growing contingent of workers. With considerable fixed assets, these enterprises have over the past many years supplied a great amount of technical equipment of a certain standard to various national economic departments and for national defense construction. About 80 percent of the total equipment of the basic national industrial departments was manufactured domestically. At the same time, these enterprises have also supplied the market with an increasing quantity of durable consumer goods. We must affirm and not underestimate the great achievements we have made and the material and technical foundations that have been formed, because in restructuring the whole national economy and carrying out technical innovations in the future we have to rely and pin our hopes on them. Belittling our ability and regarding foreign machinery as more advanced and our machine building industry as inferior is impractical and wrong.

But at the same time we must understand that the development of our machine building industry has been limited because of the effect of the mistaken "leftist" leadership and because we followed a backward foreign management system for quite a long period. There are still a number of problems even today and these mainly include dispersed management, low development of production technology and improper service orientation.

Organizationally, our machine building industry system is in a chaotic situation because management is dispersed and the departments concerned only mind their own business. Departmentally, there are the two systems of military industry and civilian industry in our country, coupled with manufacturing and maintenance systems and general equipment and special equipment manufacturing systems. Many departments across the country now have their own machine building industry. Provinces, municipalities, administrative regions, prefectures, people's communes and production brigades also have their own machine building industry, and they all have their own separate lines of business and vie with each other in turning themselves into "big and complete" and "small and complete" organizations. As a result, their economic relations, specialization and coordination have been seriously affected, and consequently a number of examples of irrationality and repetition in construction, production, scientific research and technological imports causing enormous wastefulness have appeared. For example, there were three big neighboring machine building plants in Beijing each with its own casting forging, tool, maintenance and heat treatment shops. They were developing into complete plants but this development caused serious waste of productivity and energy.

Quite a number of our machine tools are of low quality, with low efficiency and old structures. The basic technology in the machine building industry such as casting, forging, welding, processing and surface treatment has long involved backward methods. As a result, many of our products are of low quality and efficiency and consume enormous amounts of raw materials and energy. In short, the products of our machine building industry are about 10 to 20 years behind the advanced world standard. For example, our vehicle manufacturing company in Changchun was completed in 1956, and it was then more advanced technically than Japanese motor vehicle factories such as Toyota. Not long ago when a Japanese manufacturers delegation was visiting the Changchun motor vehicle plant they were surprised to find that China had such an advanced and big motor vehicle plant at that time. But what surprised them more was that after two decades and more, the output of this plant had only increased 100 percent while its key equipment, production technology and main products were basically unchanged, and its production technology was lagging far behind that of Toyota and other Japanese companies.

Most of the main products of our machine building industry have for a long time been mainly for use in heavy industry and capital construction and for high accumulation but not for technical innovation of enterprises. The usefulness of these products in agriculture, light industry, science, culture and education, urban construction and the people's livelihood has been limited. Our machine building industry is characterized by a narrow range of services, limited methods of production and an irrational structure, and consequently it has failed to meet social needs. As a result, the following situations have occurred during readjustment work. On the one hand, a number of machine building plants, particularly the key plants that are capable of increasing the productivity of heavy industry, do not have enough work to do. On the other hand, there are a number of production methods but no plant has actively carried out these methods or those plants that wanted to do the job have not had the necessary conditions. In addition, because of our limited technical level, our machine building industry is still not able to manufacture big and advanced precision products. These situations are often referred to as "sometimes not having ehough to eat but sometimes having too much."

(III)

The above-mentioned situations show that it is urgent to reorganize and restructure our machine building industry.

The basic aspect and requirement in reorganizing and restructuring our machine building industry is to realize coordination between specialized departments and economic unity so that our machine building industry will be rational organizationally; to renovate backward technology and gradually restructure the present fairly advanced technology so that the technology of our machine building industry will be gradually modernized; and to readjust the service orientation of the whole machine building industry from mainly serving capital construction to the "four services" of technical innovation of the national economy, domestic markets, expansion of exports and modernization of national defense.

Over the past few years, our machine building industry has done some efficient work in these aspects and it has made a good start. But taken as a whole, the achievements are not obvious and experiences are not adequate, and therefore it is necessary to continue to work and to explore.

(1) About Reorganization

To reorganize means to gradually break through the boundaries between regions and departments and change the situation of "big and complete" and "small and complete" and take the road of coordination between specialized departments and of economic integration. Coordination between specialized departments and economic integration are major questions that belong to the sphere of economic management and they are necessary for socialized production. Following the development of social division of labor, the specialization in the machine building industry will expand to parts and technology, and consequently enterprises will increasingly rely on each other. Objectively this requires that coordination be organized widely and economic integration be realized so as to meet the increasing needs of socialized production.

It is necessary for the guiding thought for reorganization to continue to be implementation of the principle of "bringing strong points into play, protecting competition and promoting unity" and the principle of economic rationality and production facility. Integration may take many forms. The forms of the unity that have appeared in the machine building industry include: (1) more relaxed integration such as sales, supply, export and design work of production units and user departments; (2) organizational integration among specialized products such as joint venture vehicle companies and radio set companies; (3) integration according to different basic parts, components and technical organizations. Such integration may be carried out within a region, among regions or even nationally. The forms and the size of the integration depend on the actual situation but it is advisable to proceed from a loose integration to a tight integration, from a smaller scale to a bigger scale and to gradually advance from a lower stage to a higher stage. Supply, marketing and sales can be combined first, followed by the integration of industry, trade and commerce; but the integration of staff, finances and goods and materials must be carried out later.

In order to effectively and stably promote reorganizing work, it is better to begin this work among trades and in major cities with key products of key enterprises. On the basis of study, investigations and unified planning it is necessary to set up trade organizations on a trial basis. Experiences in some localities prove that we must pay attention to the following two points in the method of carrying out restructuring work. One is to combine the method from bottom to top with that from top to bottom so as to meet local as well as overall [demands]. Another is to combine administrative methods with economic methods so as to coordinate macroeconomic and microeconomic interests. In order to ensure smooth implementation of reorganizing work, administrative intervention may be exercised as the key when necessary so as to promote economic rationality through administrative methods. When we talk about strengthening leadership over the macroeconomy, we include direct intervention by the state through administrative methods. Of course, this intervention can only be carried out under the premise of putting the interests of the whole country in the first place and of combining the economic interests of all the parties that have joined in the integrate. We can in no way "establish family links by force." In the process of reorganizing, it is imperative to follow the principle of mutual benefit and of selecting the best departments for integrating. A number of the problems arising during the course of integration usually reflect "power" and "interest." Such problems include who will lead the enterprises that have joined together, who will have the right to sell, produce and supply and to distribute profits and how to price the products. All the enterprises concerned must be equal in these respects and they must share equal interests so that they will be able to progress at the same pace. In this respect, two situations must be prevented; one is that big factories must not squeeze out small factories and the factories with ownership by the whole people must not squeeze out factories with collective ownership. Another is that big factories cannot take over the burdens from small factories and the factories with ownership by the whole people cannot take over the burdens of the factories with collective ownership out of consideration for households with economic difficulties. All these situations run counter to the principle of economic rationality and they cannot exist for long.

In the process of reorganizing, some machine building industrial enterprises will be closed down, suspended, merged or shifted to other production. With regard to industrial departments, the situation of the machine building industry is uneven, but generally speaking, the products of the industry are in excessive supply. In the past, a number of factories were built blindly. Statistics show that over the past 15 years, an average of 12 machine building factories have been built every day causing serious repetition of production. Consequently, these factories do not have enough raw materials and it is difficult for them to continue their operations. Therefore, in the future it is forbidden to set up factories arbitrarily. In addition, the factories that have for a long time showed losses rather than gains and those with small-scale production, backward technology, very high consumption of raw materials and energy, low quality and high-priced products that are unsalable must be resolutely closed down or shifted to other production. But this work involves relocation of staff and workers and therefore it is advisable to shift as many factories to other production and close down as few as possible. We can in no way advocate the method of "filling the gap" for the factories with poor economic results and no prospects; otherwise we will cause the situation to worsen. In assigning tasks it is imperative to order and arrange for goods commodities. Studies must be carried out so that we will be able to establish standard technology for our products and permit the existence of systems for production. The factories that fail to reach the defined standard will have to stop production for the purpose of readjustment. This measure will check and control building factories blindly and producing slipshod products and improve the quality and efficiency of our machine building industry.

(2) About Restructuring

In order to raise the level of the entire machine building industry, it is imperative to combine reorganizing with restructuring. As the duty of machine building industry is to serve the technical innovation of the national economy and to supply various departments with good-quality equipment, it is necessary for the industry to first of all reform its own technology.

Above all it is imperative to resort to rational technological policies. So far we have not had rational and stable technological policies for many years. At times the policies have stressed indigenous methods and at other times foreign methods, and this practice is not in accord with the needs of the era in the development of technology, nor with the conditions in our country. In restructuring technology and resorting to advanced technology we must proceed from the realities of our country. We cannot just consider our intermediate-range interests and not work hard to improve technology. On the other hand, we cannot depart from our capabilities and blindly seek advanced technology. The correct principle is that we should have advanced and economically applicable technology with economic and technical results as the key. Our machine building industry and various departments must pay attention to this aspect in carrying out technical restructuring.

Technical restructuring must also develop from a lower to a higher stage. We must pay attention to technical restructuring partially and at the same time strive to make important breakthroughs. It is necessary to combine both correctly so as to link intermediate interests with long-range interests. It is necessary to strengthen research and development work, do a good job of developing technology and technical equipment and replace old products with new ones step-by-step and in a planned way. We must also actively promote "three generations of products." That is, improve first-generation products that are now being made; trial-produce second-generation products by producing new products in the near future; and make preparations for research work for third-generation products that are to be produced in the future. At the same time, explorations must be carried out for the fourth generation of important products. It is also necessary to consider long-term tendencies and strengthen basic research work and study. In short, before a product ends its cycle of prosperity and then "decline," we must be able to produce a new product to replace it.

The quality of enterprises must be improved through technical restructuring. When we were restructuring the enterprises in the past, we often concentrated our efforts on merely increasing productivity and adding plants and equipment and personnel and we neglected the work of improving the technical level. The requirement for the present technical restructuring is more than just tapping potentials, innovating and restructuring. This requirement includes: (1) Strengthen scientific research and study and carry out technical restructuring so as to enable enterprises to produce new products to replace the old and produce complete sets of equipment. (2) Restructure technical equipment so as to lower consumption and raise labor productivity. (3) Set up an experimental base and control system so as to improve product quality and develop new products. (4) Reorganize production lines and manufacture new equipment so that our enterprises will be able to advance from producing preliminary products to producing high quality products. (5) Train personnel so as to enable enterprises to use modern management technology and improve management and the operational level. We must pay attention to and strengthen all these tasks as they are necessary for enterprises to improve their overall productivity.

In order to raise the level of the entire machine building industry it is imperative and vital to train, improve and rationally make use of the technical force. The problems of the technical force in machine building industrial departments are: First, not enough personnel; second, a low level and slowness in improving it; and third, not every one has the chance to use his talents, personnel are assigned work that is unsuitable to them or they do not have work to do or do not have a chance to carry out their roles. This situation must be gradually changed. At the same time, it is imperative for enterprises to strengthen their own scientific force and designing force and to improve the work of importing, learning from, digesting and grasping foreign technology and to combine these two aspects because this work is important in strengthening technical restructuring.

(3) About Readjusting Service Orientation

An important purpose of readjusting our machine building industry is to rationalize the standard of this industry so that it will be able to meet various social needs. To a certain extent, the correct service orientation is the premise and manifestation of reorganizing and restructuring.

Over the past year and more, the departments of the First Ministry of Machine Building have begun to implement "six changes" and "five services" to basically reflect the readjustment of the service orientation of the whole machine building industry and the readjustment of other aspects. The "six changes" are: Change from mainly serving heavy industry to also serving agriculture, light industry, urban construction and the people's livelihood; from mainly serving the building of new factories to serving old factories in tapping potential, carrying out technical innovation and reforms; from mainly being engaged in manufacturing to engaging in designing and arranging for complete sets of equipment, installing, commissioning and repairing equipment and supplying spare parts as well as training operators; from serving the domestic market to becoming active in entering the international market; from engaging in small-scale to engaging in mass production and gradually developing specialized production; from concentrating efforts on increasing the scale production and quantity to improving quality, variety, supply time and lowering costs so as to constantly improve the management of enterprises. The "five servings" are: While serving heavy industry and capital construction, also serve the needs of agriculture, forestry, animal husbandry, sideline production and fisheries, light industry, the market and the people's livelihood; serving the needs of old factories in tapping potential, technical innovation and reformation; serving the needs of the urban and rural collective economy and commercial enterprises; serving the needs of maintenance and technology in production and serving the needs of expanding exports. Practice has proved that this readjustment is very important, and if we continue with it, our machine building industry will be able to meet still better the various needs of society while it is developing normally.

This readjustment of the machine building industry must take various needs into consideration but we must also emphasize carrying it out. According to the present situation, it is imperative to grasp well the following three points: Step up technical restructuring of the existing enterprises; promote the production of industrial consumer goods and expand the exports of mechanical and electrical products. But in addition to grasping key tasks we must pay attention to other tasks. It is important to handle well the relationship between the processing industries and the basic industries and between industrial consumer goods and equipment.

It is of practical significance at present for the machine building industry to serve light industry, textile industry and to promote the production of industrial consumer goods. With increased output of industrial consumer goods, the needs of the people's livelihood will be met, the markets will become brisk, currency will be recovered, the people's income will be increased, finances will be balanced and exports will be increased to earn more foreign exchange. With all those, our national economy will be freed from the current difficulties. In addition, it is a binding duty of our machine building industry to support light and textile industries. Lenin said: "The making of the means of production is not for the sake of the means of production themselves; it is because the industrial departments that are producing consumer goods are increasingly demanding more means of production." Over the past year and more, the machine building industry has supported light and textile industries with enormous quantities of special equipment and various types of technical equipment for technical reform. In addition, according to the principle of similar production technology and economic rationality, our machine building industry has also begun processing parts for some light industrial products and producing complete sets of equipment for light industry; it has also directly produced a certain quantity of durable goods. Some localities have, through unified planning and according to the requirements of the development of light industry, shifted some machine building factories to light industrial departments to engage in producing light industrial products because their products had no definite orientation and they did not have enough work. All these measures have had fairly good results in expanding the production of light and textile industries, improving the quality of products and in reducing consumption, and therefore such measures must be continued. The basic way to support light and textile industries is to use production technology of the machine building industry, supply good equipment and create conditions for light and textile industries to advance toward specialized modernization. Even though it is necessary to shift some factories to other production, it is very important and it must be carried out in a planned way.

In readjusting the service orientation it is imperative to strengthen leadership over planning. The best way for the machine building industry to serve various national economic departments is for all these departments to have fairly stable planning or serious losses will result. Cases of poor planning have appeared time and again in the past and they must in no way reappear in the future. Measures have been taken since last year to carry out regulation by market mechanism and broaden the scope of production. Such measures are correct and they have had quite good results. Therefore, these measures must be affirmed and continued in the future. The question is to investigate well the market situation and make better predictions so that the auxiliary regulation by market mechanism can be correctly combined with the regulation by planning mechanism that plays the main role. Now various departments concerned are very enthusiastic about producing industrial consumer goods, particularly those in short supply. This is a good situation. But we must in no way do this work rashly without planning. It must be carried out carefully and according to our capabilities. Boldness in carrying out this work must be prevented. The state's unified planning and rational management are indispensable and very important, and therefore they must be strengthened.

Reorganizing and restructuring the machine building industry and readjustment of its service orientation must be considered from the important angle of improving economic results. Viewing our national economy from this angle, the present investments must bring economic results in the future. Increasing economic results is the way out for our economy. Our machine building industry must, through reorganizing and restructuring, improve the quality of its products, develop new products, improve technical services, establish additional economic departments with modern equipment to meet market demand by producing durable consumer goods, increase exports and be active in entering international markets. By doing so, not only will the level and results of the machine building industry itself be considerably improved, but also socioeconomic results will be greatly improved. This is also a target of the machine building industry in carrying out reorganizing and restructuring.

JOURNAL ON USE OF ENTERPRISE FUNDS

HK220515 Beijing JINGJI GUANLI [ECONOMIC MANAGEMENT] in Chinese No 6, 15 Jun 81
pp 37-39

[Article by Liu Chunqin [0491 2504 0530]: "It Is Necessary to Strengthen Guidance Over Utilization of Funds Retained by Enterprises for Their Own Use"--note passages within slantlines denote boldface type]

[Text] Since the expansion of enterprise autonomy in 1979, funds at the disposal of enterprises have been increased notably. The total annual balance retained by enterprises for their own allocation amounts to approximately 15 billion yuan, comprising the following items: profits retained as their own share, basic depreciation funds for fixed assets, funds for major overhauls, funds for replacement and transformation set aside according to output, income from improved assessment value of and rental from fixed assets, and new profits resulting from tapping potentials, renovation and restructuring supported by production development funds of the enterprises (according to the stipulation of Sichuan Province, this newly made profit will be retained by the enterprises for 2 years and used at their own discretion. The amount differs with the various enterprises, for some it is equivalent to 1/3 of the profits). This financial source taken as a whole is quite considerable, and its utilization exerts significant influence on the whole national economy. For this reason, in order to improve the performance of funds retained by enterprises for their own use, to promote economic development, and to achieve liveliness without chaos, it is necessary for the state to strengthen guidance and management of these funds.

To strengthen guidance over these funds retained by the enterprises for their own use means to stipulate certain rules to be followed as principles as well as to adopt certain concrete measures in regard to the allocation of these funds on the part of the enterprises without infringing on basic interests of the enterprises. In the light of the present situation of our country, it is necessary for the state to strengthen guidance in the following respects.

/1. Unify the fund categories. This is a prerequisite for compiling statistics and for carrying on supervision in regard to the allocation of the various funds, and a further step for controlling the proportion between consumption and accumulation./ Currently, in our country various categories of funds have been set up in various regions and various enterprises. Most of the enterprises have accounts for production development funds and for welfare and award funds. In addition to these, some are also keeping accounts for plant construction funds or reserve funds. Some enterprises have set up welfare and award funds for their staff and workers and have done nothing in respect to production development funds. Perhaps this is necessary in the initial stage in order to gain experience, but in the long run this should not be so. A unified rule should be made at a suitable moment. In the meantime, for the enterprises that carry on the practice of profits sharing, it is necessary to add another fund, namely the price adjustment fund. Now the state is making use of the deviation of prices from their value for the purpose of regulating the relationship between production and sales of certain commodities, and of balancing state revenue and expenditure. As a consequence, of the profits made by the enterprises, a part represents the surplus value created by the staff and workers of the enterprises, and the other part is the extra income resulting from price policies, having nothing to do with the labor of the enterprises. The purpose of setting up a price adjustment fund is to set aside that part of the profits not related to the performance of labor in the enterprises so that part of it can be turned over to the state, and the remaining part can be kept by the enterprises in the form of price adjustment funds to iron out the advantages and disadvantages within the enterprises caused by unreasonable pricing practices. Another thing to be done is to combine the housing construction fund for staff and workers and the fund for collective welfare. The combined funds can be called housing, culture and welfare funds (for the sake of brevity, they can also be called collective welfare funds). As a result, for enterprises that carry on the practice of profitsharing, there should be four funds, namely the production development fund, the housing, culture, and welfare fund, the awards fund for staff and workers, and the price adjustment fund. The enterprises that are undertaking experimental responsibility for their own profits and losses should set up another fund, a reserve fund, making five funds altogether.

The financial allocation of these funds should differ as the types of enterprises differ. In corporations and other types of combined organizations, generally speaking, plants at the basic level have set up award funds for staff and workers, housing, culture and welfare funds as well as a partial production development fund (that is, a part is turned over to the corporation for the development of major projects). As for the other funds, for example reserve funds, price adjustment funds, partial production development funds, shares of foreign exchange earned in export trade, and so on, they are left to the corporation for unified allocation. In consequence, the performance of these funds will be enhanced. Of particular significance, is the setting up of price adjustment funds in the corporations. This might provide a solution in ironing out the disparities brought about by the deviation of prices from value.

/2. Lump all the funds together./ For the trial-point enterprises, a share of the profit or profit after tax is the only source of special purpose funds for production development. The basic depreciation fund, and the income from assessment of orice of fixed assets and from rentals are set aside and kept in separate independent accounts, not included in the corresponding special purpose funds. However, in the meantime, it is stipulated that the enterprises are given the right to combine these funds with the production development fund in deployment of the funds. This being the case, why should they not be lumped together in a reasonable manner? An appropriate combination undoubtedly is beneficial to the strengthening of financial management, and better control of the enterprises as well as the social consumption and accumulation. With the combination of the funds, it should be kept in mind that they are still kept for their original purposes and are not to be used for other purposes.

1) The production development fund: This includes part of the profit share or profit after tax (not including the profit of enterprises arising from the factor of price policy, the same below), the basic depreciation fund for production equipment, income from price changes of production equipment and from rentals, replacement and renewal funds set aside according to output, and new profit arising from tapping potential, renovation, and restructuring supported by the production development funds of the enterprises.

2) The housing, culture and welfare fund: This includes part of the profit share or profit after tax, the depreciation of living facilities, the income from change of price of such facilities and the daily business earnings of such facilities.

3) The price adjustment fund: Due to the factor of price policy, the enterprises gain part of the extra profits.

4) Award fund for staff and workers: Part of the profit share or profit after tax.

5) Reserve fund: Part of the profit share or profit after tax.

As a result, with the exclusion of the above-mentioned funds, the enterprises have only one independent fund, namely the major overhaul fund, which should be kept as a special purpose fund so the present equipment may be kept in good condition, and the simple reproduction of the enterprises may be maintained.

/3. Devising a method of fund allocation with a set purpose./ This means to direct the initiative of the enterprises to the set economic targets of the state by means of economic methods. In order to attain this end, the first thing the state must do is to designate the key problems awaiting solution in a specified period. The second thing is to correlate allocation of the funds to these targets so as to stimulate the growth of the national economy.

One key problem in the development of our current economy is the shortage of energy, raw materials, and good quality and new products. Naturally, the allocation of funds of various categories should be related to these problems as much as possible. The energy products used by the enterprises are different, so are the consumption levels of fuel of the various enterprises. This makes the calculation of allocating the funds quite inconvenient. For this reason, the energy-saving and raw material consumption indicators should be replaced by production-cost reducing indicators (raw materials, fuel, and consumption of power generally comprise about 70 percent of costs). In this way, the allocation of the funds of the enterprises can be correlated with the following four indicators: Cost of production, volume of production, the rate of high quality products, and the rate of profit. The ratio of profit for each indicator should also differ. As it is more difficult to reduce costs, the ratio for profit in this respect should be larger. Since it is easier to increase the volume of production, its ratio of profit should be smaller, and consideration should be given to the question of whether the product is in short or in excessive supply in the respective profit ratios. In the case of high quality and new products, since in the early stage of their development very possibly their profits are meager, the enterprises should either be given all the profits within a specified period, or be given an encouragement profit share out of the profits of the enterprises, taken as a certain percentage of the allotment price (or wholesale price) of the products. Ultimately, the enterprise then sets aside a certain portion of its profits earmarked as its fund. However, this should not be the major part of its total funds. In this way, the enterprises are made to turn their attention to cost reduction of their products and increasing the output of products in short supply and the enhancement of their quality as well as the development of new products.

The key problems arising from the development of the national economy may change with the passage of time. By then, the allocation of enterprise funds will also change in respect to their aims and methods of allocation. To appropriately adjust the ratios of fund allocation and the targets of encouraged development is an important task in management of the leading economic bodies henceforth.

/4. The designation of fund allocation. The state gives guidance to improve effective use of the funds./ Here, first of all, the enterprises must be allowed to manage the funds, and the basic uses of the funds must be clearly specified. The purpose of this is to urge the enterprises to make good use of the funds and to devote the funds to the major targets of the state awaiting facilitation. This is a task relating to the economic policy of the state as well as a basic premise in deciding the proportions of the various funds.

At present, the old enterprises are facing two major problems, replacement and transformation of facilities and housing for staff and workers. Replying solely on the production development funds of the enterprise to replace and transform existing facilities obviously provides limited financial strength. Consequently, we must study and develop a production development fund for our enterprises which is suitable to our national condition. Study must also be made as to how to make use of other funds.

1) The production development funds should be mainly devoted to the purpose of upgrading and redesigning products. Sometimes, the upgrading and redesigning of products are mutually effected by the replacement and transformation of plant facilities. As new products are designed and developed, the old plant facilities must be transformed somewhat according to the requirements of production techniques. It should be pointed out that this is a problem of adding certain facilities that are needed, rather than an overall renovation and restructuring, still less is it a problem of large-scale expansion of production capacity in relation to replacement and transformation of facilities. Tasks in this regard will be undertaken after readjustment of our national economy and the completion of overall planning and preparations.

2) The housing, culture, and welfare funds, for the present, should be focused on dealing with the housing problem of the staff and workers of the enterprises so that their living conditions may be improved. As for the housing problems of the peasants, the problems should be dealt with by the collective and the peasants' own efforts.

3) There is no problem in regard to the award funds for staff and workers being used to give awards to the staff and workers. However, certain principles must be set. In the regulations in this regard, aside from setting limits to bonuses

granted and other matters, it should also be stipulated that enterprises be allowed to grant bonuses at the end of the year to their staff and workers. With the total bonus kept unchanged, taking part of the bonus (for example 30 percent) as a yearend bonus, perhaps, will be beneficial to both the state and the enterprises. Of course, yearend bonuses are to be granted only upon completion of certain prerequisites. One prerequisite is that the enterprise must complete all the tasks assigned to it by the state. Another is that no violation is committed in regard to financial discipline (prompt and full payment of tax and profits to the state). Without the fulfillment of such requirements, bonuses should be reduced or withheld. With such a yearend bonus, enterprises will undoubtedly be urged to improve production and management as well as mobilize the initiative of the staff and workers in keeping a watchful eye on the economic disciplines to which the enterprise must abide. In the meantime, this is a safeguard against granting bonuses for exceeding the quota before knowing the business results of the whole year.

Naturally, in order to strengthen state guidance over the utilization of funds retained by the enterprises for their own use, studies must be made and conclusions arrived at in regard to the proportions of the various funds. For example, there is the problem of the capability of the funds to make good the shortages in question, and under what conditions should such a service be given. There is also the problem of priorities with respect to the setting up of the various funds. When the enterprise earnings are not enough to cover all the funds, then which funds should be set up first, and which should follow? In short, with respect to the economic activities of enterprises that wield expanded power, the state is still groping for experience in order to provide them with guidance to achieve liveliness and to screen out chaotic elements. It is the purpose of this essay to present to the readers the author's preliminary viewpoints so that these viewpoints may be studied and discussed by the readership.

FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

CONFUSION OF MAJOR REPAIR, DEPRECIATION FUNDS DISCUSSED

Beijing CAIWU YU KUAIJI /FINANCE AND ACCOUNTING/ in Chinese No 6, 20 Jun 81 pp 10-13

/Article by Tian Chunsheng /3944 2797 3932/: "On the Nature and Control of Major Repair Funds"/

/Text/ Should the major repair funds of enterprises have the characteristics of fixed assets or those of circulating funds? This question must be clarified in both theory and practice. A popular view at present is that the expenditure of major repair funds should be charged against fixed assets along with depreciation funds. Such a view will cause not only theoretical confusion but also practical damage.

I.

People believe that major repair funds should be related to fixed assets simply because these funds, like depreciation funds, are used on fixed assets for the purpose of maintenance and preservation of their utility. This sounds plausible, but it is actually wrong. Although major repair funds and depreciation funds are both used on fixed assets, they nevertheless have different characteristics. While depreciation funds have the characteristics of fixed assets, major repair funds are of a circulating capital nature. Marx conducted a fairly detailed analysis on the different characteristics of these two funds.

First, Marx analyzed the different functions of these two funds. He pointed out that depreciation funds are intended as reserve funds to replace salvaged fixed assets. In his opinion, "the value of the fixed capital flows back to its starting point in proportion to its wear and tear in the form of a sinking fund" which "will replace the value of the capital originally invested." ("Collected Works of Marx," Vol 24, p 203) Major repair funds, on the other hand, are for necessary additional outlays to maintain the normal operation of the fixed assets within a prescribed period. "It is a question here of additional labor, without which the machinery becomes useless.... Hence it is a question of keeping the machinery literally in working order." (Ibid., p 194) The difference between the functions of these two funds can be summarized this way: While depreciation funds are used for the purpose of compensation, major repair funds are intended for the purpose of maintenance.

Second, Marx further pointed out the difference between these two funds on the basis of their turnover. He said: Depreciation funds are included in the original value of the fixed assets and, along with the value of fixed assets, are gradually converted into the value which they have helped to create in the products. Then compensation is obtained by installments from the sale of these products. When the life of the fixed assets has expired, the depreciation funds will have accumulated to their starting point and will provide the full amount of money for the replacement of these fixed assets. As for major repair funds, "these expenditures are not included in the originally advanced capital and cannot therefore be replaced and covered, at least not always, by the gradual replacement of the value of the fixed capital. For example, if the value of the fixed capital is 10,000 pounds and its total life is 10 years, then these 10,000 pounds, having been entirely converted into money after the lapse of 10 years, will replace only the value of the capital originally invested, but they do not replace the capital, or labor, added in the meantime for repairs." (Ibid., p 195) It is obvious that the major repair funds, as an additional outlay, can by no means be gradually accumulated to the point of replacing the equipment, because they are spent immediately after appropriation.

Third, judging from the use of these two funds, we can see that depreciation funds will certainly bring about the recovery, or even an increase, of the fixed assets' value (because depreciation funds have the characteristics of accumulation funds). For example, when a set of machinery has been salvaged, a new set can be bought with the depreciation funds as a replacement and the value of the fixed assets is thus recovered. However, the use of major repair funds cannot, theoretically speaking, recover the fixed assets' value, much less add to their value, because the use of such funds can only create the conditions for the fixed assets to be used up to the stipulated number of years. Even though some new elements have been added to the fixed assets, this can only embody the utility of the fixed assets within the limited period, but can neither recover nor add to their value in any way. As Marx said, fixed assets can be utilized for so many years because "this average life itself is based on the assumption that the additional capital required for maintenance purposes is continually advanced," "just as we assume, in placing a man's life at 30 years on the average, that he will wash himself." (Ibid., pp 196 and 194)

Fourth, speaking of the use of major repair funds, we can see that major repair funds (which also include expenses on medium and minor repairs) are necessary for the maintenance of regular production, including materials, wages, administrative expenses and similar outlays. Marx said: "As it is of paramount importance to remedy every damage to machinery immediately, every comparatively large factory employs, in addition to the regular factory force, special personnel--engineers, carpenters, mechanics, locksmiths, and so forth. Their wages are a part of the variable capital and the value of their labor is distributed over the product." "This labor must be continually expended in production, and hence its value must be continaully replaced by that of the products. The capital invested in it belongs in that part of the circulating capital which has to cover the general expenditure." "This maintenance work counts as current expenses and is therefore an element of circulating capital. (Ibid., pp 194-196)

By analyzing the difference between depreciation funds and major repair funds, Marx drew the conclusion that major repair funds belong to the category of circulating capital. This conclusion in no way conflicts with his famous thesis of differentiation between fixed capital and circulating capital based on the different forms of capital turnover. It has also been proved in practice in many countries for many years.

It is harmful to consider the expenditure of major repair funds as related to fixed assets. For example, some localities have ruled that major repair funds can be combined with depreciation funds; some localities have combined the depreciation rate with the major repair fund accumulation rate and looked upon this combination as a source of funds for renovation or transformation of fixed assets; some localities have combined major repair funds with production developing funds--obtained from retained profits--and the depreciation funds to be used by the enterprises for tapping potential and renovating and transforming their equipment; and some localities have used the major repair loans as investment loans instead of circulating capital loans; and so forth. On 10 November 1979, RENMIN RIBAO carried a frontpage report on the reform of the economic administration system by the Thread Reeling and Belt Weaving Company under the Shanghai Textile Bureau. The report said: "The plant has the power to combine the basic depreciation funds, the major repair funds, and the production developing funds appropriated from the company for its expenditure, thus ending the irrational situation of 'forbidding the use of vinegar money to buy soy sauce,' and helping the enterprises to tap potential and renovate and transform their equipment." It also mentioned that this reform had already been approved by the higher leadership and endorsed by the departments concerned. This certainly produced widespread repercussions. Because of the ideological confusion of major repair funds with depreciation funds, it is quite possible for major repair funds to be diverted to other uses, such as the purchase of new fixed assets and the expansion of productive capacity, resulting in damage to fixed assets from the lack of repair funds. Because of high targets and blind commandism during the Great Leap Forward of 1958, major repair funds were used on capital construction, and under the slogan "neither minor nor major wounds can justify a retreat from the firing line," many worn-out machines had to continue operating, resulting in serious breakdowns. The state was later forced to spend huge amounts on "overdue" major repairs in the subsequent years of readjustment. Even this failed to preserve the "average life" of some fixed assets. The "premature death" of these assets was a great loss to the national economy and this experience is still fresh in our memory. We must never return to the old ruts. Another phenomenon was the unjustified diversion of funds. Funds for renovation and transformation were diverted to capital construction; major repair funds were diverted to renovation and transformation; and major repairs had to be accounted for in the production costs. It is true that the need for fixed asset repairs was not overlooked; however, since major repair funds had been diverted to other uses, such expenditure could only be charged against the production cost. Thus the production cost was greatly increased and the profit greatly reduced. Finance was undermined and the scope of investment in fixed assets was enlarged. This was a hindrance to the implementation of the national economic readjustment policy.

In 1979, the open-hearth workshop of a steel plant in a certain municipality had its furnace and factory building remodeled. The bottom area of the open-hearth furnace was enlarged from 36.2 to 42 square meters; the residue-heat boiler was renovated; and some equipment for eliminating smoke and dust was added. The capacity for continuous casting was raised. According to the original plan submitted by the plant, some 8 million yuan was required. Since some 6 million yuan was to be appropriated out of the repair funds, only some 2 million yuan was to come out of the renovation funds. Yet the municipal authorities and the department in charge actually approved the exclusive use of major repair funds on what should mainly have been a renovation and transformation project. A total of 14.89 million yuan of major repair funds had to be spent on the completion of the project. Since there were not enough major repair funds, the bank had to be approached for a loan of 3.5 million yuan. The funds required for genuine major repairs had to be charged against the production cost. In another instance, a major repair required for a cupola furnace of the second converted workshop cost 3 million yuan. The plant claimed that since there was no clearcut regulation on the scope of repairs, it should be rated as a medium repair to be charged against the production cost. Such diversion of funds is by no means an isolated case, but a rather prevalent practice. As an end result, the financial income which should be handed over to the state was used for financing an unplanned capital construction project. This is one of the reasons why financial revenues cannot be increased and the capital construction front cannot be reduced at present.

II.

To distinguish between the different characteristics of major repair funds and depreciation funds and to ascertain their different uses, we should further clarify two problems of understanding--or two practical problems--in addition to what has been mentioned so far.

1. Is "major repair fund" an abbreviation for "major repair and depreciation fund?" Some comrades contended that the name "depreciation fund" was omitted only for the sake of brevity, and that such funds were mainly used to cover depreciation and therefore belonged to the fixed asset spending category. "Major repair fund" was used in the sense of "major repair and depreciation fund" by the Soviet Union in the 1950's. At that time, depreciation funds were called "basic depreciation funds," while major repair funds were called "major repair depreciation funds." Aside from the difference in nomenclature, there was also a subtle difference in financial accounting. There were then three different types of depreciation rates. The formulas of their computation are (residual value and expenses for dismantling or removal excepted) as follows:

$$\text{Comprehensive Depreciation Rate} = \frac{\text{Original Fixed Asset Value} + \text{Major Repair Expenses}}{\text{Estimated No of Years of Use}} + \text{Original Fixed Asset Value} \times 100\%$$

$$\text{Basic Depreciation Rate} = \frac{\text{Original Fixed Asset Value}}{\text{Estimated No of Years of Use}} + \text{Original Fixed Asset Value} \times 100\%$$

$$\text{Major Repair Depreciation Rate} = \frac{\text{Major Repair Expenses}}{\text{Estimated No of Years of Use}} + \text{Original Fixed Asset Value} \times 100\%$$

Second, appropriations for major repair depreciation, like those for basic depreciation, reduce the net value of fixed assets; however, if major repair funds were used on fixed assets, the net value of these fixed assets should be recovered through a certain process.

The old depreciation method of the 1950's was both complicated and unnecessary. Appropriation for repair and depreciation each year reduced the fixed assets, and when major repair funds were used on fixed assets, their original value had to be recovered. Thus the reduction and subsequent addition of value caused unnecessary complication. For a certain fixed asset, the amount of appropriation for major repairs and depreciation could not be the same as the amount actually spent. Therefore, when the fixed assets had to be salvaged after having been used for the required number of years, the natural outcome would be either an incomplete or an excessive depreciation of their original value. More important still, this old type of major repair and depreciation method was merely a formality without practical significance. Depreciation and depreciation funds reflect the wear and tear as well as the remaining value of fixed assets. If a major repair fails to supply this information, the appropriation will not be able to reflect the extent of the loss of fixed asset value; nor can it shed any light on the cost of the replacement when the asset has to be salvaged. In the final analysis, it is a type of additional outlay instead of a depreciation reserve. It takes the form of depreciation reserve only because of the need to account for it in the production cost. That is why this system of major repair and depreciation had to be reformed after only a brief existence. After the reform, the term "major repair and depreciation fund" was changed to "major repair fund;" the major repair depreciation rate was changed to major repair reserve rate; and the basic depreciation rate and basic depreciation funds were changed to depreciation rate and depreciation funds respectively. Incidentally, it may be pointed out that when some documents and articles mentioned depreciation and depreciation funds, the word "basic" was frequently used, although this was entirely unnecessary. Before the reform, the word "basic" denoted major repair and depreciation; now major repairs are no longer associated with depreciation, and the word "basic" is no longer necessary.

2. There is the relationship between the use of major repair funds and the expansion of decisionmaking power for the enterprises. In expanding the decisionmaking power of enterprises in business management, all unnecessary barriers between various types of funds should be removed. However, it would be wrong to oppose, as some sort of inhibition, the regulation that major repair funds should be used on fixed assets only. If there is no need for the major repair funds to be independently set up and used, then how can this system have been so popular in foreign countries for a full century?

There is no data for the exact year or month of the origin of major repair funds. However, we are sure that when Marx wrote "Das Kapital," there was already such an economic category. At that time, repairs were already classified as "major repairs" and "minor repairs" (ibid., p 198) and major repairs were financed by a reserve fund, based on "an average expense distributed over the average life." (Ibid., p 196) We understand that even to date, foreign countries are still using this system. The "System of Regulating Time Limits for the Use of Fixed Assets" (ADR system) issued by the U.S. Government in 1971 specifically stipulated the proportion of funds to be drawn for building up the repair reserve for various types of fixed assets, in addition to various depreciation rates and the margins of readjustment. In view of the possibility that the repair expenses may be transformed into fixed assets, a rational limit was set for the compensation of repair expenses. Expenses within the limit are transformed into fixed assets and compensated by the depreciation funds. From this, we can see that the United States not only sets up and uses the major repair funds independently, but it also exercises a very strict control over them.

Any value of fixed assets acquired through repairs would be accounted for in the depreciation fund. In sharp contrast to our system it uses renovation and transformation to protect instead of competing with major repairs. Under this ADR system, the stipulated rate of building up the repair reserve is approximately 5.8 percent. It is our understanding that the Soviet Union also revised its depreciation rate in 1975 and made separate stipulations for the depreciation rate and the proportion of major repair reserve.

Why should these countries have their self-imposed "inhibitions?" It is quite clear that finance is a reflection of the economy, and fixed assets being used must be protected and repaired. This is an objective fact. The setting up of major repair funds is decided by objective facts. If you do not recognize them and divert major repair funds to other uses, the equipment still needs repair. As a result, you are only violating the objective economic laws and will be duly punished.

Therefore, in expanding the decisionmaking power of enterprises, we should not disturb the channels of major repair funds which objectively exist. Yet we must not adopt the same overly rigid control as we did before, leaving the enterprises without any flexibility. The ideal way would be as follows:

1. We should establish and perfect a control system for the fixed assets of enterprises while implementing the policy of readjustment, restructuring, consolidation and improvement and streamlining enterprise management. This will include setting up and perfecting a system of equipment inspection and repair which will clearly define the specific economic and technical limits for major, medium and minor repairs of various fixed assets, and a system of advance inspection and repair, so that there will be certain regulations to go by and certain rules to follow. We should constantly keep the fixed assets in excellent operating condition so as to insure regular production. Major repair funds should be appropriated according to regulations so as to insure that the requirements for major repairs are met and to prevent the diversion of these funds to capital construction or to renovation and transformation of equipment. All units drawing major repair funds should not charge such expenses against production cost. Should there be any temporary shortage of major repair funds, they should apply for bank loans for this purpose, but treat them as circulating funds.

2. In view of the continual development of science and technology today, we should break through the old convention of "four originals" (original structure, original materials, original scope and original location which cannot be changed). We should permit and encourage the coordination of major repairs with renovation and transformation. If we can improve the economic effects, we should strive for a reasonable increase in fixed asset value through repair, renovation and transformation even though this may involve changes of form, location and structure. We should also strive to improve the functions of these assets through upgrading or replacement. In coordinating major repair with renovation and transformation, it should be permissible for two different funds to be combined, as practiced under the ADR system of the United States, whereby each party should be responsible for its own share of funds.

Upon introduction of the system of payment for the use of circulating capital, the enterprises will have to pay the principal as well as the interest. It would obviously be unfair if these enterprises could not use their major repair funds in the way they consider necessary. Therefore, provided funds for major repairs are assured, the enterprises should be permitted to use part of the temporarily unused major repair funds as circulating funds for other purposes. However, these funds must be returned when a major repair is required. All funds must be flexibly and efficiently used.

PRC JOURNAL ON ENTERPRISES' DECISIONMAKING POWER

HK141450 Beijing JINGJI GUANLI in Chinese No 6, 15 Jun 81 pp 24-26

[Article by Li Shayu [2621 1421 1342] and Chen Zehung [7115 3419 3163] of the Sichuan Academy of Social Sciences: "Problems in Expanding the Decisionmaking Power in Enterprises"]

[Text] The reforms of the economic system are new and some shortcomings and problems will inevitably crop up. Therefore, it is necessary to sum up experiences in economic reforms, study new situations and new problems and further perfect the various reforms. We have made tentative studies on some problems in the reforms of the economic system which need solutions. They are as follows:

1. The Problem of the Relation Between the Macroeconomy and Microeconomy

Taking the form of socialist planned economy as the prerequisite and proceeding from the expansion of decisionmaking power of enterprises, the reforms of the economic system carried out in Sichuan have focused on the distribution of economic interests, which is the crux of the matter. By expanding the decisionmaking powers of enterprises, the enterprises have been turned into relatively independent commodity producers. Having their own economic interests, they have integrated regulation by planning mechanism with regulation by market mechanism in operations and management. Thus, the enterprises have become self-operating organic bodies with both inner motivational force and external pressure for competition. The experiments over the past 2 years have reached the expected targets in the main.

Since the main subjects of the experiments were the enterprises, attention was concentrated on the economic interests of the enterprises and economic conditions for automating the enterprises. For this reason, the distinct success chalked up in the experiments in Sichuan was the mobilization of the enthusiasm of the grass roots enterprises. However, one noteworthy problem in expanding the decisionmaking power of enterprises was that while arousing the enthusiasm of the grass roots enterprises, the guidance of macroeconomic planning fell behind. Hence the economic activities of the enterprises lost to a certain degree the overall macroeconomic balance. This problem was expressed in a concentrated way in that the measures for controlling the distribution of bonuses by the enterprises could not keep pace with the situation and some enterprises expanded production in an unplanned way.

In order to solve this problem, first of all, the relation between the macroeconomy and microeconomy must be thrashed out. We hold that the relation between the two is a relation between the whole and the part, and between the general and the particular. The microeconomy is the basis of the macroeconomy while the macroeconomy is the sum total of the microeconomy. The macroeconomic movement restricts the orientation of the development of the microeconomic movement. The socialist economy is a planned commodity economy. Without the macroeconomic analysis of the total sum, the data from economic analysis of the amount of the individual sums are not comprehensive from a microeconomic point of view. Therefore, in the economic reforms, attention should be paid to the roles of both the macroeconomy and microeconomy. While enhancing the enthusiasm of the grass roots economic units, it is imperative to strengthen the guidance of macroeconomic planning and administrative intervention, integrate the macroeconomy with microeconomy and regulation by planning mechanism with regulation by market mechanism and coordinate the enthusiasm of the localities, departments and enterprises with socialist planning.

Then it is necessary to strengthen the planned guidance over regulation by market mechanism. This is not an abstract conception but rather regular work of the leading economic organs. At present, many enterprises have asked the responsible departments to supply them with information on the economic movements of the market. Of course, the leading economic organs have some difficulties in doing this at the moment, but it is entirely possible to make investigations, calculations and forecasts of the key points of investment, main projects, productive capacity and main products within the period of the plan, and the information of various localities producing goods of different types, the variations of commodity prices and the quotations on the market at home and abroad. This will enable the enterprises to understand the overall situation of market economic movements and variations in the macroeconomy, proceed from reality and work out correct operational decisions under the guidance of macroeconomic planning.

Furthermore, it is necessary to exercise guidance and control over the orientation of investment of the funds belonging to the enterprises. In this respect, the state's reinforcement of planned guidance in the macroeconomy is mainly manifested in doing a proper job of maintaining an overall balance. Attention should be paid to balancing the orientation of investment of the enterprises and the social needs. In using their own funds to expand reproduction, the enterprises should maintain a balance between the types and quantity of items produced on one hand and social needs and market demands on the other. They should also maintain a balance in the situation of production of the existing enterprises; otherwise, blindness will occur. While carrying out expansion of reproduction by extension, the enterprises should make reports and get approval from the departments concerned according to capital construction procedures and exercise strict control over administrative procedures. In solving this problem, the experience of Shanghai deserves our attention. On the basis of different bureaus, trades and companies, they carried out regulation of interests, worked out plans for tapping potential, innovating and transforming production and carried out expanded reproduction. In this way, blindness in enterprises production can be reduced.

In short, it is imperative to integrate well the reinforcement of the guidance of macroeconomic planning with the further revitalization of the microeconomy. While preventing the tendency of one-sided emphasis on independence of the microeconomy to the neglect of planned guidance, we should spontaneously prevent the tendency to overstress the importance of the guidance of macroeconomic planning resulting in excessive rigid control over the microeconomy.

2. The Problem of Defining the Amount of Economic Interests of Enterprises

Sichuan's experiments in reform took the rational distribution of the net income created by the enterprises as the core. Therefore, reforms directly involved the material interests of the state, the enterprises and the staff and workers. Judging from some experiments carried out in Sichuan, the problem of the state-run industries and enterprises having relatively independent economic interests was solved fairly successfully through the reforms of the whole economic system. But in the past 2 years, extremely sharp disputes have arisen between the financial departments and enterprises over the proportion of profit-sharing. In order to increase their economic interests, the enterprises have always persisted in having their proportion of profit-sharing increased. On the other hand, fearing that too large a proportion of profit-sharing for the enterprises will affect state revenues, the departments concerned have all along intended to reduce the proportion of profit-sharing for the enterprises. Thus, the problem of how to decide the amount of the independent economic interests of enterprises was put forward to the public. We hold that the basic factors for determining the economic interests of enterprises are the position and powers of enterprises as relatively independent commodity producers. The economic interests of enterprises should be commensurate with their powers and economic responsibilities. The interests of enterprises consist of three key elements. They are as follows: First, the enterprises' funds for developing production. The amount of these funds is decided by the degree of power possessed by the enterprises for carrying out expanded reproduction by intension and extension. Second, the enterprises' funds for collective welfare: The amount of these funds depends on the extent of the development of the enterprise collective welfare and the financial strength of the enterprises. Third, the enterprises' funds for rewarding the staff and workers: Apart from the amount of funds stipulated by the State Council, the enterprises that have been run really well should be allowed to retain more profits to reward the staff and workers. In addition, we are of the opinion that in defining the economic interests of the enterprises, the financial revenues and expenditures of our country in a certain period should be taken into consideration. Generally speaking, the amount of economic interests of the enterprises is directly proportionate to that of the state financial revenues. At present, when the financial revenues of our country are somewhat strained, it is entirely justifiable for the enterprise to have a smaller economic interest. According to estimates, in Zhongqing the profits retained by the enterprises after paying industrial and commercial taxes will be 15 percent by or even before 1985. Based on our investigation of 10 enterprises in Chengdu, the retained profits can only reach 16.2 percent. The economic interests of more than 400 enterprises participating in experiments in expanding decisionmaking power last year in Sichuan did not surpass 20 percent of the profits they generated. This not only ensures financial revenues for the state but also enables the enterprises to have the economic conditions for their own development, and the interests of the staff and workers are taken care of as a result.

The enterprises participating in the experiments in Sichuan first took into consideration their vested interests in defining the proportion of distribution of interests between the state and enterprises. Of course, it is undoubtedly a good thing to stimulate their enthusiasm for participating in the experimental work. However, it must be pointed out that the protection of vested interests is fundamentally wrong. It is known to all that after the smashing of the "gang of four," the production of many enterprises was restored to normal, with the result that production grew very fast and output and profits increased by a wider margin. Under these circumstances the experiments of expanding decisionmaking power of enterprises were carried out. Planned profits were very often on the low side but the profits in excess of the plan were relatively high. Therefore, if the interests gained by the enterprises in the experiments of expanding decisionmaking power in the past 2 years are consolidated and what is more, protected, two problems will emerge: One is that the regulation of economic interests among the state, the enterprises and the staff and workers will be hampered. Things will go all right with the ever-growing production and ever-increasing profits of the enterprises, but things will become worse when production falls and profits decrease due to subjective mismanagement or to objective causes such as lack of energy and raw materials. Under these circumstances, although the income of the state and enterprises decreases simultaneously, the state gets less revenue than the enterprises. In order to protect the vested economic interests of the enterprises, bonuses cannot be reduced, with the result that there are decreases in the income of the state and the enterprises but the economic interests of the staff and workers are not readjusted accordingly. The other problem is that consolidating and protecting vested economic interests will make it difficult to carry out regulation of the amount of economic interests among enterprises. In the initial stage of the reforms, little consideration was given to the external conditions of the enterprises, for instance, the condition of equipment, the quantity of fixed assets, the condition of resources and transportation. In particular, prices were irrational and only a rough proportion (with only slight differentiations) was determined in drawing on a certain percentage of profits, resulting in unfairness in profit-sharing among the enterprises and even resulting in a situation in which with relatively poor management and administration and little exertion of labor, some enterprises got more profits than the others. In order to change this situation, it is entirely correct for the economic departments and the theoretical circles to propose using economic levers such as a regulatory tax to ensure fairness in profit-sharing among enterprises. But some enterprises used "protecting their vested interests" as an excuse and refused to accept this necessary regulation of interests, thus putting themselves in a passive position. This situation must be changed.

3. The Problem of the Limits of Authority for Enterprises to Expand Reproduction

In the experiments in Sichuan the enterprises have been given greater decisionmaking power. Economic results have been good for the past 2 years.

The problem now is that there is one-sidedness in the enterprises' understanding of market demands. This will probably lead the enterprises to blindness in making investment decisions on expanding reproduction. Judging by the experiments carried out in Sichuan, generally speaking, being afraid of taking risks, the enterprises make careful decisions on matters of investment, for they mainly use their own funds with bank loans as a supplement. On the whole, there is little blindness in the enterprises' carrying out of the projects of expansion of reproduction by intension such as the renewal of equipment, the tapping of potential, renovating and restructuring, but there is relatively great blindness in a few enterprises' carrying out of expansion of reproduction by extension such as making investments externally, forming joint ventures and building new factories. As a result of this, some comrades in the economic circles hold that since the power to make decisions to expand reproduction was given to enterprises, great expansion of capital construction has occurred. This "caused greater disproportions in the national economy" and "brought new difficulties to the work of readjustment." They maintain that expanded reproduction should be concentrated in the hands of the state while enterprises can only carry out simple reproduction within the limits of the existing funds. "Apart from the retained profits to be used for public welfare and for bonuses, that portion to be used to expand reproduction should be centralized." We cannot agree with these opinions.

First, as for the blindness that occurred in a few enterprises in expanding the decisionmaking power of enterprises, a concrete analysis should be made. We should not attribute the excessive expansion and the disproportions in the national economy to the enterprises having the decisionmaking power to expand reproduction. It is known to all that both the excessive expansion of capital construction and serious disproportions in the national economy existed long before the expansion of decisionmaking power of enterprises.

Second, there is no inexorable relation between the blindness occurring in expanding reproduction by the enterprises and the state-run enterprises having decisionmaking power to expand reproduction. In many enterprises involved in expanding their decisionmaking powers in Sichuan, there was no blindness in expanding reproduction. Even though there was blindness in a few enterprises in expanding reproduction, the main reason was that the responsible economic departments lacked planned macroeconomic guidance. So long as the information system is set up and emphasis is put on strengthening the guidance of macroeconomic planning and the necessary administrative intervention, it is more advantageous than disadvantageous to let the enterprises have the power to expand reproduction.

Third, blindness in capital construction is closely related to the implementation of a two-level financial system and blindness occurred in the production of the localities and commune-run or brigade-run enterprises. We should not attribute these two kinds of blindness to the enterprises having the power to expand reproduction.

We advocate that enterprises should have the power to expand reproduction. However, in the period of economic readjustment, owing to a lack of medium and long-term state plans, a sound market information system, normal and timely economic calculations and forecasts and other factors, the enterprises' power to expand reproduction should not be excessive. So long as they have the power to carry out expansion of reproduction by intension, that is, the power to renew machinery and equipment, raise the scientific and technical level of the staff and workers, transform the existing production [words indistinct] by themselves. The power to carry out expansion of reproduction by extension and use the funds, that is, the power to enlarge the scope of production, add new means of production and expand the fields of production can be utilized within the limits of a province on the basis of unified planning, coordination and balance based on different bureaus, trades and companies. In this way, the achievements can be doubled: the blindness in expanding reproduction by some enterprises can be reduced and the enterprises' development on their own as relatively independent commodity producers can be ensured. This will do no harm.

NATIONAL POLICY AND ISSUES

'JINGJI YANJIU' DISCUSSES COMMERCIAL FORMS

HK141521 Beijing JINGJI YANJIU in Chinese No 6, 20 Jun 81 pp 57-61

[Revised draft of article by Gao Dichen [7559 3321 7115] of the Finance, Commerce and Economics Research Bureau of the Chinese Academy of Social Sciences dated November 1980: "On the Objective Basis for the Existence of Various Commercial Forms"]

[Text] In the course of readjusting and reforming the economy and for the purposes of fully utilizing the markets, enlivening the circulation of commodities and accelerating economic development, the localities, be they the urban areas of the rural villages, have all felt that the circulation process could not cope with the needs of production and that the commercial network was not broad enough and was unable to meet the consumption needs of the people. Hence, simultaneously with increasing commerce under the system of ownership by the whole people, energetic efforts have been made to promote the development of commerce and service trades under the system of ownership by the collectives and also those under the system of ownership by individuals. Concerning this new development, people have ventured diverse views. Some believe that this is an important measure suited to the level of development of the productive force of our country at the moment and to the people's livelihood. However, some think that this development is incongrous and in fact a retrogressive step which in the foreseeable future would mean going through socialist restructuring again and thus involve a waste of time and effort.

In this way, actual practice in economic readjustment and economic reform has brought up a problem in economic theory, namely, what is the objective basis for the existence of various commercial forms in the process of commodity circulation? (Note: Here the concept of commercial forms includes the various types and forms of commerce and commercial enterprises under the various forms of the ownership system, such as wholesale, retail, specialized stores, comprehensive stores. Concerning this problem, a conclusive viewpoint to the effect that the various commercial forms in the circulation process were determined by the forms of the ownership system of the production materials in the realm of production used to prevail. It is necessary now to make a renewed study of this viewpoint which was once considered more or less conclusive.)

First, in theory this viewpoint takes production as the determinant factor for exchange or circulation. In simpler terms, it implies that the ownership system of the production materials in the production sector determines the ownership system in the circulation sector. In other words, that production determines exchange may be interpreted to mean that whatever the form of ownership in the production process the same form of ownership is obtained in the circulation process. For example, industrial production under the system of ownership by the whole people must be complemented by state-operated commerce, and agricultural production under the system of ownership by the collectives must be complemented by rural commerce under the system of ownership by the collectives. The so-called three-commodity circulation channels in our country were in effect formed on the basis of this theory.

Second, this viewpoint was closely related to a seriously erroneous tendency in the economic theories of our country. In these economic theories, when explaining the problem of the reciprocal relationship between production relations and the productive force and after having basically completed the three big socialist restructuring processes, there has been a steadily widening departure from the basic Marxist doctrine that production relations must be suited to the nature of the productive force and that changes in the development of the productive force determine changes in the development of the production relations. The theory that changes in production relations can promote the development of the productive force has been unduly emphasized. At the same time there has been an increasing tendency to propagate one-sidedly the belief that the bigger and the more thorough the public ownership system of the production materials the better and more advanced it is. The departure is even wider in the circulation sector. From a system of three circulation channels and commercial forms under two kinds of ownership there evolved a diminishing number of commercial forms. The reasoning was that the fewer the better, preferably one commercial structure only, on the pretext that it would be much easier to work with only one structure, that one structure would result in savings on expenditures, and so on. Thus, administrative orders were issued to "elevate" the status of the ownership system, that is to convert ownership by the individual to ownership by the collectives and to convert ownership by the collectives to ownership by the whole people. It was thought that such conversion would be more "fashionable" and that the sooner they were carried out the greater the possibility of their becoming advanced models. This tendency gathered momentum as time passed. By the time of the disturbances under the Lin Biao and Jiang Qing counterrevolutionary cliques it had developed to preposterous proportions, and it appeared then that only through continually changing the production relationships and continually changing the form of ownership of the production materials could the productive force attain a continuous development. This was equivalent to changing from what originally occupied first place and was the determinant factor to something in second place which played only a minor and subordinate role. It was equivalent to changing from the principle of the productive force determining the production relations to a new and contrary principle of the production relations determining the productive force.

This kind of economic theory was immensely disruptive in the socialist construction enterprises of our country. Actually, it constituted a "leftist" error in economic construction and should be considered an important source of the ideology and reasoning responsible for the many ups-and-downs and massive upheavals in the development of the national economy. This theory made a particularly striking appearance in the circulation sector where its disruptive effects were especially serious. It may be said that although in the production sector there was a continuous expansion in the scope of the public ownership system and a continuous increase in the extent of public ownership, the existence of the system of ownership by the collectives was still permitted. However, in the circulation sector, it developed that not only was the system of ownership by the individual completely obliterated but also there were no grounds for the continued existence of the system of ownership by the collectives. Quite obviously, this type of theory provided a theoretical basis for a single type of operation in the circulation process and also provided the ideological background for the coming into vogue of the practice of persons playing the dual role of bureaucrats and merchants.

It is precisely under the guidance of this type of economic theory that after 1958, on various occasions rural supply and marketing cooperatives were merged with state-operated commercial units, that cooperative stores (units) were either elevated step-by-step or "reached the sky in a single bound," while individually-operated commercial units were either rejected or banned altogether. By the time of the great Cultural Revolution, little was left of the commerce and service trades under the system of ownership by the collectives, while commercial units and service trades under individual ownership were banned for being capitalistic and were obliterated in certain localities. In 1957, the total number of individually-operated commercial units in the whole country was 3.59 million; by 1978 it had dwindled to only 610,000. In Shandong Province, in 1957 there were over 70,000 collectively-owned units doing business or engaged in the service trades; by 1978, the number had dwindled to only 500, while the number of business or service units operated by individuals was reduced from over 90,000 to only 274. In Shenyang Municipality, in 1957 there were 13,588 cooperative stores (units) and individually-operated commercial or service units, but by 1970 not a single individually-operated unit was in existence while only 1,080 cooperative stores continued to exist. However, these stores were "collectively-owned" in name only; in fact they were branches of state-operated stores. Since the many commercial forms of varied economic composition were reduced in a short time to state monopoly commerce, the impetus of competition in commodity circulation disappeared. This, plus the rigid and stereotyped control system, the numerous administrative procedures, and the excessive control over the form and planning of the purchasing and marketing of commodities, practically reduced the originally lively and ever-changing circulation process to mere "exchange" operations that were ossified and lifeless. The results were the serious impairment of the development of production, while in the circulation sector laziness and bureaucratism were fostered. The people suffered great inconveniences in their everyday lives.

The theoretical viewpoint holding that the form of the ownership system in the production sector determines the form of the ownership system in the circulation sector has no basis in historical fact. In the historical development of the commodity economy, commodity producers under any form of ownership system always prefer to have many different commercial forms to market their products. Similarly a commercial form under any system of ownership habitually handles commodities of many and different owners. This is because the circulation process of commodities comprises numerous exchanges of commodities and the process in the exchange of commodities has all along taken place between a variety of owners of commodities; otherwise it would not be an exchange of commodities in the real sense. Commerce plays the special role of the intermediary in the exchange of commodities between the variety of owners in the circulation sector. This intermediary role of commerce between different owners of commodities determines that a commercial form must serve the circulation of commodities produced under different systems of ownership and cannot confine itself to serving the circulation of products of only one system of ownership. Therefore, the viewpoint that the kind of system of ownership in the production sector determines the kind of system of ownership of the commercial units in the circulation sector, and the conclusion that the kind of system of ownership in production must be complemented by a similar kind of system of ownership in the circulation process are not in accord with the historical facts of commodity circulation and have no basis in theory.

In view of the above, how do the rule that production relations must be suited to the nature of the productive force and the rule that the development level of the productive force determines the form of the ownership system assert themselves in the circulation sector? In other words, what is the relationship between the various commercial forms in the circulation sector and the development level of the productive force?

A simple answer is as follows: The forms of the system of ownership in the circulation sector are also determined by the state of development of the productive force. At the current stage of the level of the productive force there must be various types of commercial forms because only in that way can the objective demands of the current development level of the productive force be met. Such an answer is obviously correct in principle. However, if we further ask, in the final analysis, what particular level of the productive force requires what particular form of the system of ownership in commerce, the above answer would appear to be too generalized. This kind of answer does not give people a clear understanding and an available objective basis concerning the development and reform of the commercial forms. At the same time, historically the evolution of the commercial forms has shown that such a generalized answer cannot really solve the problem. In a feudalist society, commodity economy was undeveloped, the degree of the socialization of production was low, and exchanges were carried out on a relatively small scale. Under the condition of the social productive force being at a low level, there were huge commercial capital engaging in purchasing and marketing activities on a nationwide scale and big merchants enjoying exclusive selling rights, but there were also the rank-and-file medium-size and small merchants, street peddlers and roving peddlers carrying their goods on their shoulders all of whom played a part in the commodity exchange activities of the circulation sector. In a capitalist society where large-scale socialized production has developed rapidly and in a modern capitalist society wherein the productive force is highly developed and backed by a firm basis of mechanization and automation, there can likewise be large monopoly commercial capital operating on a nationwide scale and even in international markets, big department stores, and big retail companies in control of the urban and rural markets and large supermarkets. There may also be medium-size and small business, family business, small merchants and small roving peddlers. In Japan, the total number of people employed in small businesses stores of less than four people each (in fact the great majority are in the nature of family business) is over 80 percent of the entire social commercial network. In the United States, Britain, France and other countries, the number of small commercial units is relatively small, but it is still about 40 percent of the total. Although there have been many ups and downs in the economic development of our country over the past 30 years, we may still say that the level of our productive force is far above that in the initial period of the liberation. However, the realities of our economic life require that in the process of readjusting and reforming the economy we change the situation of a monopoly type of commerce and restore that of the coexistence of various commercial forms similar to the situation in the 1950's. In addition to increasing state-operated commerce, we must on the one hand develop collectively-owned commerce and service trades and on the other hand restore individually-owned commerce and allow these types of commercial and service activities to participate in the circulation sector. We should not only permit the coexistence of various forms of economic composition in the sector of commodity circulation but also promote the development of various forms of businesses such as large, medium-size and small businesses, specialized businesses, businesses engaged in all types of activity and roving businesses. We should also promote various types of commercial operation methods, so that they may form a variety of commodity circulation channels and thus ensure the smooth flow of goods in the entire social structure. If we do not do this we will be unable to enliven the markets, enliven the entire economy or vigorously promote the development of production and meet the consumption needs of the extensive masses of people.

The historical phenomenon of the coexistence of various types of commercial forms in commodity circulation as mentioned above and the reality of economic life in our country both demonstrate that the forms of the system of ownership of the production materials in the production sector do not determine the forms of the system of ownership of commerce in the circulation sector. The ultimate function of the level of development of the social productive force in determining the form of the system of ownership of commerce is neither simply nor directly manifested. In reality, the state of development of the social productive force frequently plays its functional role in the relationship of the system of ownership in the circulation sector and in the commercial forms only after having gone through various intermediate, transitional links and along an extremely winding path.

This being the case, how is the ultimate function of the development of the social productive force in determining the commercial forms in the circulation sector manifested concretely? Let us analyze this problem from the three different angles of consumption, circulation and production.

First, from the standpoint of consumption, the products of a producer of commodities must pass through the exchange process to be transferred to the end user. If a commodity is not wanted for consumption, or if the consumer demand for it lessens resulting in difficulties in marketing it, then the reproduction of this commodity cannot be pursued consistently. Hence, the consumer demand of the social structure cannot but play an extremely important and direct determinant role in the organizational forms and operational methods of commerce which has as its first and foremost function the marketing of commodities. The role played by consumer demand in the social structure in determining the commercial forms is principally manifested by the evolution and changes in consumption. In the realities of economic life we can readily discern that changes either in the consumption level or in the consumption structure and reforms in either consumption methods or consumption habits all directly produce new demands on the commercial forms and thereby necessitate appropriate changes in these forms. (1) Mankind's level of consumption constantly rises in accordance with production development and increases in monetary income. Such changes in mankind's consumption level can directly bring about changes in the organizational forms of commerce and of the service trades. For example, following the increase in the consumption level, the people's demand for durable consumer goods may sharply increase. This in turn requires the setting up of specialized businesses to handle the management of durable consumer goods. Simultaneously, as a result of the increase in the volume of such durable goods as television sets, washing machines and refrigerators, various kinds of repair and other service units must be set up. If changes are not made in the commercial organization forms to suit these demands and if there are no additional or new servicing facilities, then it will be difficult to satisfy the new consumer demands arising from an increase in the consumption level. (2) Changes in the consumption structure can also directly require corresponding changes in the commercial forms. Constant changes in the consumption structure of the society accompany the rise in the consumption level. Such changes are not only seen in the changes in the relative proportion which food, clothing, articles of daily use and housing occupy in the gross consumption level but are also reflected in the demand for concrete kinds of commodities. This may be seen in the constant increase in the demand for high-grade commodities and in the more intensified selection of commodities in the purchasing process. In turn, this requires the existence of big department stores and various kinds of specialized businesses which engage in large-scale operations and which are financially strong and have a plentiful supply of manpower, in order to meet the consumer demands which constantly rise to higher planes. In recent years, the "supermarkets" found in nations of a relatively high economic development level are precisely a new commercial form appearing to suit the changes in the consumption level and the new and ever-rising demands of the buyers. (3) Changes and revisions in consumption methods and consumption habits also have direct effects on the commercial forms. In the course of socioeconomic development, the consumption process constantly displays the tendency of being dispersed and divided into small segments. This tendency is not only seen in the increase in the number of family units, the decrease in the number of members of each family unit and the steady dispersal of consumption units but also more importantly in that with regard to commodity requirements, consumer demand for general and common kinds of goods has steadily decreased while the demand for specialized commodities has constantly increased. Following the rise in living standards, this phenomenon is all the more evident in the demand for variety, color and style in the commodities. A clear illustration can be found in the changes in taste in clothing. With the improvement in living conditions, demand for clothing of fixed specifications and ordinary colors (blue, white and gray) will steadily decline while that for tailored suits will greatly increase. For this reason, the tailoring trade (including the garment processing trade and the relevant commercial establishments) must adapt to such changes and in processing and making garments, a study must be made not only of the special features of a certain category of users but also of the individual's likes and dislikes. In organizing the processing trade and clothing supplies, large plants for processing garments should be established to engage in large-scale production of ready-made suits, and specialized clothing stores must also be set up to fill the general consumer needs. At the same time, in order to satisfy in a lively and flexible way the different and special tastes and demands of individual consumers there must be tailoring establishments which have their businesses in front and their workshops in back, and small collectively-owned tailoring establishments as well as tailoring units run by individuals which combine the business and the household in a single unit. Changes in consumption habits similar to those bringing about the dispersion of units in the tailoring trade will, following social development, occur in respect of other commodities. In the organizational forms of commerce this will result, on the one hand, in the emergence of big and specialized stores, and on the other hand in the appearance at every street corner in cities and towns and rural villages of medium-size general stores, small stores, goods pavilions, and mobile stands for goods selling. Not only will we need big commercial enterprises or specialized companies which have big capital, have a large concentration of manpower (such as the state commercial enterprises at present) and which are capable of handling large-scale purchasing and marketing activities both within the country and abroad, but we will also need small commercial units which require little capital and employ few people (such as the current collectively-owned and individually-owned commercial units and service trades). In this way, the ever-changing consumer demands can be met automatically and in a lively way, and the supply of commodities can be well organized.

As we all know, consumption is determined by the development of the productive force. Be it the elevation of the consumption standard, or a change in the consumption structure, or a change in the consumption method and consumption habits, the cause may be traced to the economic development of the social structure and may be attributed to the natural result of the development of the social productive force. Therefore, in the last analysis, the direct role of consumer demand in determining the commercial forms may be interpreted as the manifestation of the determinant role of the productive force. In other words, the role of the productive force in determining the economic structure and the organizational forms of commerce is indirectly reflected in consumer demand.

Second, let us look at the problem from the special aspects of commodity circulation itself. Commodities have their own special requirements as soon as they leave the production process and enter into the circulation sector. These requirements or demands come mainly from two directions, namely, the innate physical property of the commodity and its socioeconomic attributes. Let us take the innate property of a commodity. The definite technical conditions governing the period of time a fresh and easily perishable commodity can be preserved is an absolute limiting factor for this commodity in circulation. The more readily perishable a product is and the more quickly it must be consumed, the shorter is its circulation time. Just as Marx said: Commodities relying principally on being marketed locally can achieve the greatest development only in densely populated areas. Commercial units handling this kind of commodity must be flexible and lively in their structure and form of organization. They must have relatively stable circulation channels comprising a main channel and branch channels fully coordinated with each other and permitting the free flow of the commodities and must also have supply points which are rationally distributed. In addition, they must have a highly efficient organizational system and operational methods, such as the "one-dragon system" of coordinating production, transportation and marketing, in order to suit the objective demands of this type of commodities and so that they can reach the consumers as soon as possible. Contrarily, in the case of durable consumer goods which take many years to be completely consumed, the concentrated operation of specialized businesses is needed so that the buyer may have the freedom of choice in purchasing the goods. In addition, such stores must be supplemented by an appropriate network of repair and servicing units. Thus, the concrete organizational form of commerce must be suited to the special points of circulation determined by the innate property of the commodity and these special points are closely related to such other factors as whether production of the commodity is concentrated or diversified and whether its consumption is seasonal or nonseasonal. In the event that the commercial form is not suited to the special demands of commodity circulation, then it will not be possible to organize well the exchange process of these commodities. In turn, production development will be impeded and consumer demand cannot be satisfied.

Besides the innate nature of the commodities, the socioeconomic attributers of a commodity also determine and influence the special points of commodity circulation and thereby exercise control over the relevant commercial organization forms. The so-called socioeconomic attributes of a commodity refer to certain special operational laws of commodity economy, such as the law of exchange at equal value, the law governing competition, the law of supply and demand, and so on. The commercial forms must be in accord with the objective demands of various commodity economic laws in operation in the course of the circulation process. The choice of the commercial structure and commercial form must help in breaking down barriers in the localities and in ensuring the smooth flow of commodities. It must also help in getting rid of management monopolistic practices and encourage the commercial enterprises to compare their performances and vie with each other, to ensure competition and provide the commodities with an active and enlivened market. Furthermore, it must help in bringing about an equilibrium in supply and demand of the commodities, and achieve the objective of taking the shortest time and incurring the least expenses in transferring the commodities from the production sector to the circulation sector. Besides commercial enterprises of multiple economic components, in the urban and rural areas in our country such commercial forms as trade warehouses and large trade centers are still in the stage of development. They are products arising from the demands of the special features of the commodity circulation itself.

Third, from the standpoint of production, commerce is the product resulting from the development of commodity production and the need for the exchange of commodities. It performs the special function of an intermediary in the exchange activities among the producers of commodities. It provides central facilities for various producers to pursue their exchange activities and effects enormous savings of time for the producers of commodities engaging in the exchange of their products. In this way, it promotes the development of commodity production. However, following the development of socialization of production and following the development of a highly mechanized and automated productive force, big modernized enterprises and big producers of commodities have begun to set up their own marketing facilities and sell their products directly to the consumers without passing through the intermediary link of commerce. In certain developed capitalist nations, the production enterprises not only set up their own marketing structures but also set up research organs on commodity marketing to study market conditions and to forecast changes in the supply and demand of commodities. They not only market their own goods inside their own countries but also set up marketing organs abroad to sell their products. The self-marketing of products by large enterprises represents a new economic phenomenon under the conditions of a high-degree of development of the present-day productive force. In terms of speeding up the turnover of funds and shortening the circulation period, this appears to be a rational and natural development. Naturally, not all enterprises can rely on their own resources to market their products. The great majority of the enterprises still have to use commerce as the intermediary to dispose of their products in different directions. From this it can be seen that historically the development of the productive force brought about the birth of commerce, while the development of the modern productive force has enabled a portion of the products to skip over the middle link of commerce and brought direct exchanges between the producers or between the producers and the consumers. That is to say, the development of the productive force directly influences the forms of exchange in commerce, determines whether the exchange of commodities must have commerce as the intermediary link and determines whether or not commerce should exist. At the same time, the development of the productive force can also directly influence the organizational forms of commerce. For example, following the development of the productive force and the increase in the variety and output of the commodities, the need for many medium-size and small businesses scattered on the street corners of cities, towns and the rural village emerges. There also arises the need for more large commercial enterprises which have even greater operational capacity to enlarge the scope of marketing of the commodities so that the steadily increasing volume of commodities may be dispatched to more distant and broader consumption areas. In addition, the development of the productive force can also influence the organizational form of commercial labor. Indeed, with the appearance of new business machines and their wide adoption by the commercial enterprises, changes will definitely occur in the organizational form of labor in commerce in regard to the sale of commodities and such other aspects as transportation, loading and unloading, warehousing, storage and packing.

In summary, we can see that the factors determine the economic structure in commerce and the commercial forms are complicated and many-sided. There are factors concerning consumer demand, commodity circulation and production. These factors are the natural results of the determinant function of the social productive force and are the concrete manifestation of the productive force influencing the commercial forms through various kinds of intermediary links and following a zigzagging and indirect course. Therefore, in theory there is no basis for the assumption that the system of ownership in the production sector determines the commercial forms. Neither is there any basis for such viewpoints which conclude that the fewer the commercial forms and the more simplified the structure the less trouble involved and the greater the economy effected on the assumption that the larger and the more thorough the public ownership system of the production materials the more advanced it is. All these assumptions are found in practice to be unsuitable to actual economic life which is complicated, ever-changing, lively and resplendent in many ways.

Under the conditions of the public ownership system being in operation and enjoying the upper hand and viewed from the standpoint of the objective demands of commodity economy, the newly developed economy under the system of ownership by the collectives will for a rather prolonged period of time coexist with the economic components under the system of ownership by the whole people. In this way, they can compare their performances and help each other advance, thus promoting the development of the entire economy. As for the small portion of commercial units and service trades under the system of ownership by the individual, since they are engaged in operational activities under the condition of the public ownership system occupying the dominant position in the economy, the emerging new economic conditions may make it possible for them to go on the road of socialism without having to pass through the cooperativization process. The realities of economic life have made it abundantly clear to us that by means of joint operation of system of ownership by the whole people and the system of ownership by the collectives, the individual economy can proceed just the same on the road of large-scale production under the public ownership system. Naturally in this connection experiences have yet to be gained from actual practice.

At present, our country is in the process of further readjusting the national economy. To readjust well the economic structure of commerce and to organize well the circulation of commodities constitute important tasks in this connection. In readjusting the economic structure of commerce, we must develop multiple commercial forms. Not only must we develop state commerce and commerce by supply and marketing cooperatives but also vigorously develop new commercial units and service trades under the system of ownership by the collectives. In addition, certain individually-owned commercial units and service trades must be restored and developed. We must develop big and specialized businesses but also have our cities, towns and rural villages dotted with medium-size and small commercial stores, roving peddlers and vendors stands. We must vigorously develop various kinds of economic forms and at the same time organize direct commodity exchange activities among the producers. All these are necessitated by the demands of the realities of our economic. The demands emerge from the production side, from the consumption side and from commodity circulation itself. Therefore, the development of various kinds of economic components is not a step backward. On the contrary, it precisely fits in with the present state of development of the productive force in our country, is advantageous to production and circulation, and is the demand of consumption by the individual and the production process. Hence, it is beneficial to the smooth progress of our country's socialist reproduction movement at the present stage.

FINANCE AND BANKING

NEED FOR CONTINUING POLICY OF CURRENCY WITHDRAWAL STRESSED

Beijing ZHONGGUO JINRONG /CHINA'S BANKING/ in Chinese No 7, 4 Jul 81 pp 22-23

/Article by Wang Xiyi /3769 0823 5030/: "It Is Necessary To Uphold the Policy on Withdrawing Currency From Circulation"/

/Text/ Due to the implementation of the policy to carry out further economic readjustment and to achieve political stability and unity as decided by the Central Committee Working Conference, the national economy has developed in harmony and the market has become brisk since the beginning of this year. In appearance, the situation of currency withdrawal is good. Despite the increase in production and the brisk market, however, some comrades have different views on whether the circulation of currency has returned to normal and whether continuing to uphold the policy on withdrawing currency from circulation as decided by the Central Committee is still necessary. Besides being a matter of policy, currency circulation also concerns the implementation of the policy of national economic readjustment. Here are my superficial views on this question.

1. The situation of currency withdrawal in the first 5 months of this year has been fairly good. However, the situation of a market with excessive banknotes accumulated over a long period has not been basically changed.

Compared with the same period of 1980, the amount of currency withdrawn from circulation in the first 5 months of 1981 showed an increase of more than a billion yuan. This was an initial success in the implementation of the policy of national economic readjustment. However, judging from this year's planning for economic readjustment, the situation of currency withdrawal is by no means ideal, and market conditions characterized by excessive banknotes in circulation have not been basically changed. First, if we review past experience, it will be seen that currency was usually withdrawn in the first half and issued in the second half of each year. There should be a little more withdrawal in the first half before there can be a suitable amount of issuance in the second half of the year. Thus the situation of currency circulation can only be judged from an overall survey of the whole year instead of only the first half of the year. Second, if we review the ratio between currency withdrawal in the first half and currency issuance in the second half of each year in the past, we will see that the ratio of withdrawal in the first half of this year was low. In 1979, it was 41.37 percent; in 1980, 40.82 percent; and in 1981, only 38.98 percent. (Based on figures released by the end of May, because in June every year, there have been only minor issuances and withdrawals. Thus the figures in the first 5 months basically reflect the situation of the first half of every year.) This means that according to the historical pattern, the currency withdrawal in the first half of this year is not ideal. Third, the people's purchasing power left over from 1979 and 1980 was increased by 82.7 percent over that of the past several years. It is necessary therefore to have a larger supply of commodities on the market to meet the social demand. According to a preliminary estimate by the departments concerned, there should be some 3 billion yuan's worth of such major items as sewing machines and bicycles available throughout the country this year. The state is now speeding up the production of consumer goods for daily use, particularly these major items. Yet it is difficult to meet the social demand in time in view of the people's greatly increased purchasing power. At present, there is generally a shortage of commodities on the market, and in some places, the scale of rationing is on the increase. There are even isolated cases of blackmarket dealings in ration coupons because of the serious shortage of material forces to support currency withdrawal. From all this we can see that the market condition with excessive currency in circulation has not been changed and that continued adherence to the policy of currency withdrawal is necessary.

2. There has been increased currency issuance in the countryside, where the need to solve the problem of commodity shortage is keenly felt.

Since the Third Plenum of the party, the correct policies have been carried out in the countryside with the result that all five undertakings /agriculture, forestry, animal husbandry, sideline production and fishery/ are now flourishing. The peasants' income has been increased, their living conditions have been improved, and purchasing power in the countryside is rapidly rising. According to a preliminary estimate, the rural commune members' currency holdings in 1980 were increased by 30.56 percent over the previous year, while the holdings of enterprises and establishments operated by communes and production brigades were increased by 43.14 percent. From January to May 1981, the cash spent on the procurement of agricultural and sideline products increased by 22.5 percent, and financial payments in the form of both credit and cash in the countryside also increased by 22.3 percent. However, from January to May 1981, the state supply of commodities to the countryside declined by 1.8 percent. This problem deserves the attention of the leadership at various levels and the departments concerned. If there are insufficient commodities to be supplied to the countryside and to help in the withdrawal of currency, the peasants will not be able to buy what they need with their money. This will be a legitimate cause for complaint and will affect their morale. Therefore, in organizing the withdrawal of currency from circulation and the increase of commodity supply, we should first bear the countryside in mind and pay particular attention to the supply of construction materials and industrial goods of daily use in the countryside.

3. Upholding the policy of currency withdrawal is in line with the requirements of economic readjustment.

Currency circulation in the market is a comprehensive reflection of the national economy as well as the result of a combination of economic factors. Since further readjustment of the national economy has been carried out for only half a year, the economic problems have not been basically solved and the task of economic readjustment has not been accomplished. In such circumstances, currency circulation in the market cannot completely return to normal. The problems of currency circulation are mainly attributed to the 10 years of turmoil and cannot be completely solved in several months. Normal circulation in the market can only be gradually accomplished along with the progress of economic readjustment.

The national financial statements of receipts and payments have shown deficits in the past several years, and bank overdrafts alone were more than 17 billion yuan. As we can see, there are some problems in bringing about a balance of payments this year. The foundation is not quite firm and great efforts are still required. The first several months showed financial surpluses mainly because of the curtailment of expenditures. However, the income from some main sources was lower than that of last year. Under the present system of monetary control, the financial situation has not basically improved and therefore the issuance of currency cannot entirely conform to economic principles, and normal currency circulation in the market cannot be maintained.

There are also problems in production and circulation as reflected by the situation of bank credit, because the four "continueds"--continued production of goods already in excessive supply, continued procurement, continued stockpiling and continued grant of loans--still exist. This will upset the credit balance and increase the issuance of currency.

From the standpoint of commodity prices, we can see that administrative intervention this year has basically checked price inflation. However, the problem has not been basically solved, because prolonged price control with administrative methods cannot produce long-lasting effects. This also reflects from another angle the abnormal situation of currency circulation in the market.

According to the trend of currency issuance in the second half of this year, it is likely that more currency will be issued in the second half of this year than in the same period of last year. A preliminary estimate has shown that even though great efforts are being made to withdraw currency from circulation and to strictly control irrational currency issuance, it will still be difficult to keep such issuance in the second half of 1981 at the same level as that of the same period in 1980. This means that we will have to do better than what was planned by the state at the beginning of this year. Then the retail sales price index will be reduced from 7.53 to less than 7 yuan, or close to 6 yuan, which is fairly low. Even though certain new elements in the course of economic development may affect the amount of currency in the market, currency circulation in the second half of 1981, as shown by these circumstances, cannot completely return to normal.

In short, it is still necessary to continue the implementation of the policy on withdrawing currency from circulation in view of the actual situation of currency circulation and the need to meet the requirements of economic readjustment. The banks, on their part, should continue to implement the resolution of the State Council concerning the tight control of credit and strict restriction of currency issuance. While on the one hand tightening their control of credit and strictly restricting the issuance of currency, they should, on the other hand, be careful in stimulating the economy by supporting the increase of consumer goods of daily use and construction materials for the countryside, assisting in the development of service trades, and promoting procurement by the commercial departments. Thus they will provide greater material strength for the withdrawal of currency from circulation. Any control which should be tightened must be tightened, and every effort should be made to stimulate whatever should be stimulated. They should issue currency only for economic, but not financial, requirements. All these are principles which must be upheld in banking.

BRIEFS

GUANGDONG REVENUE--By the end of June, Guangdong Province had fulfilled 53.26 percent of the quota of revenue in the annual budget which was adopted by the provincial people's congress. The amount of revenue in the first half of this year was 11.89 percent more than in the corresponding period of last year. The province increased its revenue in this period by 220 million yuan. The province's total industrial output value in the first half of this year was 11 percent greater than in the corresponding period of last year. The province has conducted a large-scale inspection of tax evasion and arrears of taxes. The province fulfilled 55.4 percent of the quota for collecting taxes from industrial and commercial units in the first half of this year. The amount of such taxes was 14.16 percent more than in the corresponding period of last year. [HK030902 Guangzhou Guangdong Provincial Service in Mandarin 2330 GMT 8 Jul 81]

GUANGXI SAVINGS, LOANS--Since the beginning of this year, the credit cooperatives in the rural areas in Guangxi region have done well in commune members' savings and issuing loans to support production. By the end of June, the amount of rural commune members' savings in the region was some 59 million yuan more than at the end of last year. The region fulfilled 86.7 percent of the quota for this year's savings. The region issued loans of some 81 million yuan in the same period. The amount of loans was some 2 times greater than in the corresponding period of last year. Yulin Prefecture has established some 1,900 credit service stations in its 2,062 brigades to facilitate commune members' depositing and withdrawing money. The amount of commune members' savings in the prefecture by the end of June was some 28 million yuan more than at the end of last year. The prefecture overfulfilled its quota for commune members' savings this year by 4.3 percent. [HK030902 Nanning Guangxi Regional Service in Mandarin 1100 GMT 10 Jul 81]

HEILONGJIANG REVENUE PLAN--By the end of June, Heilongjiang Province had fulfilled over 51 percent of the 1981 municipal and county-level revenue plan. The province's industrial output value increased 1.6 percent and commodity sales increased 11.5 percent compared with the corresponding 1980 period. [SK080546 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 7 Aug 81]

GUANGDONG URBAN SAVINGS DEPOSITS--In the first 6 months of this year, Guangdong's savings deposits in the urban areas had increased by more than 379 million yuan, up more than 167 million yuan compared with the same period of last year. By the end of last June, the total amount of savings deposits in the urban areas in Guangdong had reached 1.82 billion yuan. [HK120446 Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 13 Jul 81]

LOW INTEREST LOANS--Beijing, 2 Aug (XINHUA)--Low-interest loans will be issued for the expansion of traditional trade of minority nationalities and the production of their traditional goods, according to the People's Bank of China. In a recent decision, the bank says that it will give priority to the enterprises producing such goods in Hohhot, Lanzhou, Chengdu, Kunming, Guizhou, Lhasa, Yanji, and four other centers when they solicit circulating funds or short and medium-term loans. The decision says that the monthly interest will be 0.33 percent as against 0.42 percent for other industrial and commercial enterprises. Commercial enterprises and marketing cooperatives with financial difficulties or collective handicrafts units in the areas inhabited by minority nationalities will also be given low-interest loans. ENERGY

BRIEFS

NORTHEAST POWER OUTPUT--Hydroelectric power plants of China's Northeast Electric Power Network have improved their economic management and stepped up power generation. As of 1 August they fulfilled this year's quota of generating 3.45 billion kw/hr of electricity, an increase of 26 percent compared with what they generated in the same period last year. [Beijing Domestic Service in Mandarin 1600 GMT 14 Aug 81 OW] --Shenyang, 25 Aug (XINHUA)--By 1 August, the Northeast China Power Network had already fulfilled its hydroelectric power generation plan for this year. The total power output was 3.45 billion kwh, topping that of the same period last year by 26 percent. [Excerpts] [OW270615 Beijing XINHUA Domestic Service in Chinese 1323 GMT 25 Aug 81]

SHAANXI PETROLEUM PRODUCTS--The amount of petroleum supplied to Shaanxi Province in the first half of this year was less than in the corresponding period last year. The whole province has saved 9,900 tons of all kinds of petroleum products. Of them, some 4,000 tons were gasoline, some 4,000 tons were diesel oil and some 1,000 tons were lubricant. According to incomplete satistics, from January to May this year, 14 transport companies in the province, prefectures and municipalities saved some 469,000 kg of petroleum products. [HK280219 Xian Shaanxi Provincial Service in Mandarin 0500 GMT 20 Aug 81]

HENAN ELECTRICITY OUTPUT--All power plants of the Henan electricity network generated 7.2 billion kilowatt-hours of electricity quarterly in the first half of this year. Their electricity output in the first half of this year was 215 million kilowatt-hours--3.08 percent more than in the corresponding period of last year. They fulfilled more than half of their quota for electricity output in the first half of this year. [HK030902 Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 8 Jul 81]

LIAONING POWERPLANTS--Hydropowerplants under the northeast power grid had prefulfilled their annual output plans by 1 August, increasing power output by 26 percent over 1980. [Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 6 Aug 81]

NEI MONGGOL COAL MINE--A new open-cut colliery with an annual capacity of 1.2 million tons was recently constructed and put into operation in the mining area of Wuhai Municipality, Nei Monggol. Verified coal reserves are 91 million tons and workable reserves 78 million tons. [SK091215 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 8 Aug 81]

HEILONGJIANG POWER CONSTRUCTION--Harbin, 27 Jul (XINHUA)--Two major thermal power plants are under construction in Heilongjiang Province. Generating units with a total capacity of 400,000 kilowatts are to be installed this year, accounting for 40 percent of the country's total, according to the provincial power department. One plant, in Hulan Ergi, southwest of Qiqihar, will have a capacity of 600,000 kilowatts, and will be the biggest in western Heilongjiang. A 100,000-kilowatt generating unit went into operation recently at the other plant, in Mudanjiang City. Supplementary projects, including a 220,000 volt transmission line linking the power grid in eastern Heilongjiang and Harbin and a 400-kilometer-long 220,000 volt transmission line linking Hulan Ergi, Daqing oil field and Harbin, are also under construction, the department said. The plants will help reduce electric shortages in Heilongjiang, one of China's major industrial and grain-producing centers. [OW031441 Beijing XINHUA in English 0219 GMT 27 Jul 81]

HENAN OIL ECONOMY MEETING--The Henan provincial flood control command, the provincial agriculture committee, the provincial agricultural machinery bureau, the provincial commerce department, the provincial supply and marketing cooperative and the provincial petroleum company recently held a joint on-the-spot meeting in Xuchang on economizing on diesel oil in the rural areas. The meeting pointed out that the province now has some 61,000 large and medium-size tractors, some 120,000 hand-held tractors, some 540,000 diesel engines, some 7,900 generator assembling units, some 6,400 motor vehicles for agricultural use and some 16 million horsepower of power-driven machinery for agricultural use. The amount of diesel oil consumed only by this power-driven machinery last year accounted for 73.7 percent of the total amount of diesel oil consumed by the whole province last year. A fairly large number of agricultural machines leaked. The investigation revealed that some 6,000 metric tons of diesel oil leaked from large and medium-size tractors every year. The meeting demanded that the province teach the masses to save diesel oil, establish oil economy leadership groups at all levels, implement the system of being responsible for a task until it is completed with the supply of a fixed quantity of oil, sum up progressive experience in saving oil, carry out technical innovation and reduce the consumption of oil to a minimum. INDUSTRY

PRC JOURNAL ON SUBSTITUTING TAXES FOR PROFITS

HK190528 Beijing JINGJI GUANLI in Chinese No 6, 15 Jun 81 pp 44-47

[Article by Shanghai Light Industry Machinery Corporation: "Do A Good Job of 'Substituting Taxes for Profits' and Promote Production Increase and Income Increase"--passages within slantlines denote boldface]

[Text] The Light Industry Machinery Corporation of Shanghai (hereafter, the acronym LIMC is used) is a trial point authorized in 1980 to try out "substituting taxes for profits and assuming responsibility for one's own profits and losses." LIMC was also changed from an administrative corporation to an enterprise corporation. The following is a general picture of what happened to the corporation as a trial point in a year's time.

(I)

LIMC originally had 40 plants. It is a specialty corporation with light industry machines as its main product line. Among its products are paper-making machines, printing presses, centrifugal pumps, pharmaceutical machines and so on, which can be divided into 25 main categories comprising some 420 products. With the convocation of the 3d plenary session of the 11th Party Central Committee in 1979, LIMC regained its historical record-high levels in most of its major technical and economic indicators.

For 1980, the main content of the experimental program was "substituting taxes for profits" (for the sake of brevity, we call it "tax reform" hereafter), which was a reform in financial management. As practice indicates, this reform has played an important role in giving play to the inner motivating forces of the enterprise, arousing the initiative of the basic-level cadres and masses in developing production as well as in increasing production and income, promoting improvement of business management of the enterprise, tapping potential, improving economic results and guaranteeing the increase of state revenue as well as its constancy and timeliness. The major technical and economic indicators of the corporation in 1980 were furthered developed and improved in comparison with 1979. Total output increased 13.6 percent over the previous year's figure. The total value of products for civilian use increased 11 percent as compared with the previous year. As for quality of performance, there were 15 grade one products according to the assessment of the bureau in charge and 35 such products according to the assessment of the corporation. There were three excellent performance plans and all were successfully completed, and 96.96 percent of the product contracts were completed. In comparison with the previous year, profits increased by 17.2 percent, production costs of comparable products decreased by 2.65 percent (after removing the factor of the price increase of raw materials), and the turnover of the circulation fund quota was reduced by 13 days.

Due to the development of production, the reduction of costs and the increase of profits, the results of more revenues for the state, larger profit share for the enterprise, and more income for the staff and workers have been achieved. Of the total accumulation of the enterprise for that year, 85.1 percent went to the state and 14.9 was kept by the corporation as profit share. Of the incremental accumulation over that of the previous year, 55.3 percent went to the state and 44.7 percent was kept by the corporation as profit share. The state's revenue from the corporation increased nearly 10 percent in comparison with the previous year, and profit shares of the corporation increased almost 70 percent (comparisons made according to comparable specifications).

Of the profit share, 41 percent went to the production development fund which increased the most correspondingly, both the welfare fund and bonus fund increased. On the average, the bonuses for all the staff and workers of the corporation increased 24.7 percent as compared with the previous year. The above-mentioned facts indicate that the direction of "tax reform" is a correct one, and its effectiveness has been obvious.

(II)

The "substitution of taxes for profits" means that instead of making the original payment to the state treasury in the form of taxes and profits, the enterprise makes a unified payment of five taxes (industry and commerce tax, real estate tax, license tax for vehicles and boats, regulation tax for income and earnings tax) and two fees (the fee for keeping fixed funds and the fee for keeping circulation funds). As an enterprise, LIMC operates on the basis of unified control and independent accounting for all levels, as far as its financial system is concerned. The corporation operates on the basis of independent accounting, as do its plants. The tax reform experimental program takes the 40 plants as an entity. According to specific provisions, the real estate tax, license tax for vehicles and boats, industry and commerce tax, and income regulation tax are to be paid directly by the plants, while the earnings tax is to be paid in advance by the plants and collected and settled by the corporation. Then the two fees are to be paid by the corporation out of profits after taxes, and the remaining net profit share is to be kept by the corporation and divided among the three funds according to set ratios. The purpose of making such rules is: (1) to ensure that the production development fund set aside from the profit share can be used in a relatively centralized way on important concerns of the industry such as technological improvements and environmental protection; (2) to enable the corporation to take responsibility for managing the welfare and bonus funds, and to resolve the problem of income disparity as well as other problems in order to give full play to the proper role of the headquarters of the corporation.

In light of the above-mentioned requirements, the corporation has formulated the temporary measure of "profit sharing" to be followed by the plants. The following are the important points of the measure:

(1) //Internal distribution in relation to delegation of authority:// Regarding delegation of authority, in principle, authority already vested in the plants is not to be taken back by the corporation. The authority of the plants can only be expanded and not reduced. The additional authority given to the corporation is to be gradually delegated to the plants in accordance with the prevailing circumstances. Regarding the three funds, most of the welfare and bonus funds are to be kept by the plants, and 40 percent of the production development fund is also to be kept by the plants. As for the remaining part, it is to be kept by the corporation, unified arrangements are to be made, and use of these funds by the plants is available at a cost. Besides, the retained portion of basic depreciation is increased by 10 to 20 percent (large plants may retain 60 percent and small plants 70 percent) so that there is a corresponding increase of authority to use the plant renovation and transformation fund.

(2) //The measure for distribution should be designed to encourage to the maximum the initiative of the staff and workers of the plants.// In 1979, just as the profits of the various plants differed so also did the retained profit shares. On these grounds, in regard to the staff and workers welfare and bonus funds set aside respectively by the various plants, instead of adopting a unified approach for all plants by directly correlating the profit share with earnings, the method of integrating the fixed profit share and the proportionate profit share was implemented.

The actual way of doing this is as follows: The corporation examines and fixes the respective earnings base (profit minus the regulation tax) and the profit share base. Of the profit share base, the equivalent of 11 percent of total wages is set aside as the welfare fund, and 8 percent of the average standard wages of staffs and workers is set aside as the bonus fund. Both are taken as fixed shares and set aside monthly without being affected by fluctuations in earnings. The rest of the profit share base (the total profit share base minus the fixed share) is to be examined severally, and a share rate is to be fixed based on the earnings base, known as the proportionate profit share. The fixed share and the proportionate share are to be evaluated and set aside. This provision will enable those plants with lower earnings than in 1979 to suffer less from the effects on their profit shares and to project their profit shares from excessive decline.

(3) //Those plants which had earnings in excess of the 1979 base were restrained to a certain extent in regard to their fixed shares.// In order to remedy these adverse effects and to arouse their initiative, these plants can set aside an above-quota profit share. In consideration of the necessary distinctions to be made in regard to the subjective and objective factors in business management of the plants and the differences of their respective 1979 bases, readjustments have been made to the above-quota profit shares of certain plants to make their share higher or just a little higher than the normal share so as to resolve the problem of unequal distribution.

(4) //With the passage of the distribution measure, plants that had higher profit shares were protected from acquisitions by the state. As for the small number of plants that had lower profit shares in comparison with the previous year for objective reasons, the corporation gave them subsidies out of the collective reserve funds.//

(5) //Payment of the fees for the corporation's keeping the two funds does not imply that the corporation assumes sole responsibility.// After the verification and assessment of assets and supplies in 1980, if the state funds kept by the various plants were shown to have increased or decreased, corresponding changes were made with respect to their profit share.

This temporary measure will remain unchanged for 3 years, and all the units concerned are requested to make trial calculations in accordance with the tax reform. In the meantime, the corporation's "finance and accounting department may make temporary rules for accounting matters" and specified special forms for monthly profit reports. All these measures are to be carried out in a unified manner within the system of the corporation.

(III)

The three striking changes in the corporation and its plants following the experimental program were:

(1) //Accompanying the relatively independent economic benefits for the enterprises, the motivation of the staff and workers to increase production and income was greatly heightened.//

The "tax reform" measure ascertains the definite ratios for the distribution of earnings of the corporation by way of "fixing the proportions." According to the tax reform program and the stipulations made by the corporation regarding distribution of profits, if the tasks of the plant being roughly known, it is possible to calculate the profits of the plant and the bonus for the staff and workers after tax payments. In comparison with the profit-sharing measure, the plant has the advantage of not having to worry about making excessively large increases in production and income in the current year, which may form a large base detrimental to future benefits. This is most obvious in the changes of plants operating up to the capacity. Take the Shanghai machinery factory for making plastics as an example. Its profits amounted to 1.64 million yuan in 1979. At the beginning of 1980, 1.8 million yuan was reported as the planned target for profits. According to the regulations of the enterprise funds, the maximum bonus level was reached, and there was no incentive for tapping potential, even though there was some room for it. After the implementation of the "tax reform," the concern about unfavorable profit shares resulting from "linking rations" was eliminated, and the motivation to increase income for tapping potential was greatly enhanced. The actual profits for 1980 topped 2.67 million yuan, an increase of more than 50 percent compared to the previous year, and an increase of 48.33 percent over the originally planned target. For another example, certain factories were in difficult positions with respect to increasing production and income. In 1980 they were facing the unfavorable prospect of price decreases for their products and price increases for raw materials; hence their concern about a drop in profits and decline of profit shares and bonuses for their plants. For a time, their initiative for increasing production and income was hampered. After the "tax reform," they realized that the increase of income meant increase of profit share, and the larger the increase of income, the larger the profit share. They delved into their actual circumstances, repeatedly made careful calculation of their accounts, and found a definite direction and targets for themselves. This aroused their initiative to increase production and income. The Shanghai battery-making machinery factory rallied the masses and took the measure of producing more parts, making savings on funds, reducing costs, promoting contests, carrying out extensive renovation, improving the bonus system and so on. On this basis, increase of production and income was also achieved. Profits made that year surpassed the planned target by 60 percent and more than doubled in comparison with those of the previous year (all items calculated in comparable terms). In addition, there was a small number of small factories whose profit levels were affected by objective factors such as variations in product variety and insufficient production tasks. The profit targets assigned them by the corporation were lower than those of the previous year, and they lacked enthusiasm. After implementation of the tax reform, they were still beset with worries. However, timely studies were made by the corporation. In the spirit of the relevant documents issued by the State Council, the following measure was taken valid only for the year 1980 for the benefit of these factories: If the planned targets were achieved, bonuses would be kept at the previous year's level; if above-quota profits were made, above-quota profit shares would be given. (All these funds to remedy the problem of gaps were taken from the collective funds in the custody of the corporation, and the other plants were not affected with respect to their due share.) As this supplementary measure made clear the target to strive for and the corresponding benefits to be gained, under the guidance of the factory the initiative of the broad masses of the staff and workers was accordingly aroused.

That factories with differing conditions can achieve the end of increasing income all the same demonstrates that since the "tax reform," experiment, the economic responsibility, efficiency and benefits of the plant and those of the staff and workers have been brought more closely together. The plants are no longer worried about "flogging the fast," nor are they worried about a rise of profits not being followed by corresponding increases in bonuses. Furthermore, by making calculations they can know the amount of corresponding economic benefits brought about by the economic results achieved as well as how to achieve better economic results in order to strive for greater economic benefits. In comparison to the situation prior to the experiment, it certainly can be said that the self-motivation has been enhanced and the initiative to increase production and income has been greatly heightened.

(2) //Attention is generally being paid to market sales by the enterprises, economic budgeting and control are being emphasized, bonus plans improved, and efforts made to tap potential in business operations and management to bring about income growth.//

As estimated in terms of the 1979 sales profits rate of LIMC, keeping the state funds in use at a constant level, from now on, one-third increased profits as a result of increased production and income and one-half of the increased profits due to reduction of costs can be retained by the enterprise. If the state funds in use are reduced, the savings as a result of cutting expenses in this aspect will all go to the enterprise. In order to achieve better economic results, great attention has been paid to business operations and management by the corporation as well as by the plants. First of all, a business service department has been set up in the headquarters of the corporation, and the sales personnel of the various plants have been organized and a team of 70 specialists set up to undertake market surveys and to ensure good market forecasts. At present, integrated sales organizations have been set up in Hangzhou, Wuhan and other places. The preliminary research report of the corporation has indicated the direction and target for product replacement and renewal and development of production variety as the means to enhance its predominance in the production of light industry machinery. With regard to overall quality control, effectiveness has been achieved, first with regard to spare parts and then with regard to complete machines. The precision of production assembling, the efficiency of assembling, and the capacity of complete machines have been enhanced. With regard to economic accounting and the problem of integrating value analysis and value engineering, the corporation has conducted two training courses successively. The first group of plants in which economic accounting was introduced has already seen the effects the four other plants which tried value analysis in order to reduce production costs have also achieved some good results. In 1980, the planned number of manhours devoted to the products of the corporation as a whole was reduced by 1.7 million hours, and hourly labor costs per machine were reduced by more than 10 percent compared with the previous year.

In order to further enhance the incentive of the staff and workers, to produce and to save, the plants made serious studies regarding the allocation of bonuses, some new methods were adopted, bonuses were correlated with economic performance of the producing departments as well as with the individuals so that the principle of distribution according to work could be implemented and egaltarianism be overcome. For example, in the case of the synthetic plates plant, the bonus system was used flexibly and encouragement was given in numerous ways, thereby yielding good results. In the case of above-quota production bonuses for hot pressed plates, profits increased by 100,800 yuan in 9 months, and a bonus of 420 yuan or 0.4 percent of the profits was granted to the participating workers. In the case of key tasks such as machining the pedestals of hot grinding machines, bonuses were granted to three workers in the total sum of 25 yuan only. In return, a solution was found for the problem of progress in material processing and the loss of 1,000 yuan that could be incurred in melting was averted. In addition renovation, savings, security, quality and so on were greatly encouraged, and good economic results were achieved. The Huai Hai [3232 3189] casting factory implemented a bonus system of three fixes (fixed person, fixed output and fixed bonus), two guarantees (guarantee of production and quality) and one clearing (clearing of daily tasks) for its sand-clearing group and has achieved the end of strengthening production and economic responsibility system in the group. In the first month of trying out the system, production exceeded the planned target by 10 percent. This put an end to the passive situation of the sand-clearing process lagging behind which caused overstocking of unfinished products. As a result, castings were delivered on time. This not only accelerated the inflow of funds but also satisfied the needs of customers with respect to completing sets of equipment. There were 10 comrades in the group. An extra bonus of 37.62 yuan was granted, and overtime pay was reduced by 197 yuan for that month. So the outcome was beneficial for the factory, individual workers and the customers.

(3) //With the implementation of profit-sharing as a result of internal accumulation, the enterprises have more funds at their disposal to deal with certain urgent needs and problems.//

In the meantime, as a result of the distribution of funds, the sense of responsibility to pay taxes in accordance with tax codes has been heightened, and the collection of government revenues has been stabler, more reliable, and timelier. As the enterprises are maintaining the production development fund, the basic depreciation fund no longer has to be turned over to the financial authority of the state and can be used according to plans for developing potential, carrying out renovations and transformations as well as developing products in short supply and trial-producing new products. Besides, this fund can also be used in tackling the three waste products and reconstructing dilapidated buildings. Furthermore, the welfare fund from the profit-sharing may have a credit balance after regular expenses have been paid. This can be used to construct housing for the staff and workers.

While the profit shares of enterprises are to be accounted for and set aside, emphasis is also given to the recognition of tax laws. Originally, taxes paid by the corporation's plants comprised only 15.8 percent of the total funds turned over to the state. As a result of poor operation and management of the plants or of the misallocation of funds, payment of profits to the state was often in arrears. This was detrimental to the inflow of state revenues. After the adoption of "substituting taxes for profits," corporations that were in arrears in the payment of profits to the state were liable for penalty payments as stipulated by law, and such penalty payments were not allowed to be included as part of the costs. This stipulation impelled the enterprises to abide strictly by the tax laws and to improve management of their funds. Since the implementation of the experimental program, payments in arrears of profits to the state have been eliminated on the whole, and the inflow of state revenues has been timely. At present, with the exception of the earnings tax, the four taxes and two fees due to the state from the enterprises, which amount to 64.4 percent of the total, are not affected by the performance of the enterprises and fluctuations in their costs. This further ensures the stability of the inflow of state revenues.

(IV)

Practice indicates that achieving notable results was also accompanied by the emergence of many problems awaiting improvement and investigations. The following are the more serious ones:

(1) //"Enterprises' responsibility for their own profits and losses" has not been achieved in name nor in reality.//

Up to now, LIMC has been conducting the experiment according to the tax reform plan authorized by the Ministry of Finance, in which the requirement that enterprises take responsibility for their own profits and losses as stipulated by the state economic commission is not included. As a consequence, the enterprises have been considering whether to select a larger profit share or a smaller one. No consideration has been given to what should be done in the case of losses. If losses do occur, the worst that could happen would be the halting of bonus payments and an unfavorable effect on welfare. Government subsidies can still be counted on to tide over the losses. If "taking responsibility for losses" falls on the LIMC, it will lack the necessary conditions to achieve this end. The reason is that with the exception of financial power which has been expanded, every little change or practically no change has occurred with regard to the powers relating to supply, production, sales, personnel, other materials and so on in the experiment. If an enterprise can neither run its own business independently with a free hand nor administer the necessary rights of management within the enterprise, naturally it cannot take up the responsibility for bearing business losses. For this reason, the corporation is pleading with its superiors at all levels to give them support in the realization of the due delegation of power as stipulated by the relevant documents issued by the State Council in 1980, in order to create the appropriate conditions for the enterprises to "take responsibility for losses."

(2) //As the distribution plan of the state and the enterprises uses 1979 as the base, and in the situation of growing market competition, the enterprise that is used as a trial point finds itself in unfavorable position.//

In 1979, LIMC reaped the largest profit; the corporation scored a profit rate on sales amounting to more than 25 percent. Profits must be maintained at this level henceforth to put the corporation in an advantageous position. Beginning with the second quarter of 1980, the machinery industries all over the country turned towards the production of light industry products, thereby intensifying market competition. Pricing is an important aspect of competition. In the case of products with high profit rates, factories not enlisted in the experimental program were in a position to sell at lower prices, as they were not encumbered by the restriction of a high base. On the contrary, if LIMC were to lower their prices in order to be competitive, its profit share would have been adversely affected. This unreasonable situation faced by plants undertaking the experiment has not been dealt with so far. Obviously, the plants taking part in the experiment find themselves in a disadvantageous position when they compete with plants not participating in the experiment.

(3) //The income regulating tax correlated with the volume of sales is detrimental to the development of new products.//

Generally speaking, the costs of new products under trial production or small-batch production are comparatively high. Since their selling prices are to be pegged at a high level, their profits are bound to be low. Accordingly, an income regulating tax comparable to that of old products should not be levied on them. So far no immunity has been granted to the manufacturing of new products with respect to the income-regulating tax. In the case where the profit rate of a product for sale on a trial basis is lower than the income regulating tax rate, the enterprises will be reluctant to develop new products in order to avert business losses. Without the development of new products to carry on the process of replacement and renewal and the development of new varieties in order to meet the needs of the society, in the end, the market will be lost and the development of production hampered. This will be detrimental to the interests of the state, the enterprises and the individuals. Therefore, application of the income regulating tax should be made more lenient. For example, immunity should be given to products for sale on a trial basis and reductions should be granted for products for export and low-priced products as well as for those products liable to the increase of overall enterprise accumulation after cutting their prices. In this way, the income regulating tax will be able to better play its role as an economic level.

INDUSTRY

BRIEFS

JIANGSU LOCAL INDUSTRY--Nanjing, 8 Aug (XINHUA)--The total value of products turned out by various enterprises run by communes and production brigades in Taicang County, Jiangsu Province, reached 97.04 million yuan during the period from January to May this year, an increase of 29 percent over the same period last year. The total value of consumer goods produced by various enterprises in the county since the beginning of this year has reached more than 61 million yuan, an increase of 14 percent over the same period last year. [Beijing XINHUA Domestic Service in Chinese 0105 GMT 8 Aug 81]

SHANGHAI TV SETS--Production of television sets in Shanghai increased from 140,000 in 1979 to 710,000 in 1980. Production in 1981 is expected to exceed 900,000 units. [OW111109 Shanghai City Service in Mandarin 1130 GMT 9 Aug 81]

JILIN INDUSTRIAL OUTPUT--The industrial output value of Jilin's first light industrial enterprises in the first 7 months of 1981 was 1.27 billion yuan, an increase of 10.1 percent over the corresponding 1980 period--62.3 percent of the annual plan. Of the 54 major products, 41 increased in output. Other products in short supply also markedly increased. Bicycles increased 39.1 percent; sewing machines, 28 percent; wristwatches, 51 percent; clocks, 28 percent; sugar, 45.7 percent; and beer, 18 percent. Textile products such as cotton yarn, cotton cloth, printing and dyeing cloth, chemical fibers, knitted goods, and woolen goods also increased slightly over the corresponding 1980 period. [SK150930 Changchun Jilin Provincial Service in Mandarin 1100 GMT 14 Aug 81]

FUJIAN INDUSTRIAL PRODUCTION--As of the end of July workers on the industrial front in Fujian Province fulfilled 58 percent of the annual production tasks in terms of total output value, increasing by 3.3 percent as compared with the same period last year. They fulfilled 60 percent of the annual quota for light industry products. Light industry products now account for 65.3 percent of the total value of industrial production in the province. During the first 7 months of this year bicycle production increased by 150 percent as compared with the same period last year, radios increased by 190 percent and sewing machines increased by 45.5 percent. [OW150302 Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 14 Aug 81]

NEI MONGGOL BRASS FOUNDRY--A new brass foundry, the first of its kind in Nei Monggol, was put into operation in Hohhot 30 July. The production capacity of this foundry is 1,000 tons and annual output value is expected to be 700,000 yuan. The state invested 250,000 yuan in building the foundry, expecting to earn this sum back in 1 year. [SK091215 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 8 Aug 81]

GUANGDONG INDUSTRIAL OUTPUT VALUE--Since the beginning of 1981, industrial production in Guangdong has set new records every month. The province's gross industrial output value has now fulfilled 51 percent of the plan for the whole year, showing an increase of 11 percent compared with the corresponding period in 1980. The output of 21 kinds of consumer goods increased considerably. Output of bicycles increased by 25.2 percent, sewing machines by 15.6 percent, watches by 23.1 percent, television sets by 278.7 percent, radios by 88.9 percent, recorders by 89 percent, electric fans by 417.7 percent, washing machines by 207.2 percent, electric meters by 56.3 percent and cameras by 58.4 percent. Output of sugar, cigarettes, leather and furniture also increased tremendously. In 1981, a number of heavy industrial enterprises were shifted to production of consumer goods. In the first 6 months, the proportion of output value of light industry in relation to all industries increased by 16.9 percent. [HK180840 Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 9 Jul 81]

SICHUAN LIGHT INDUSTRIAL PRODUCTION--The No 2 light industry system's enterprises in Sichuan Province incurred serious losses in the big floods. According to incomplete statistics, 17 percent of the total number of enterprises suffered floods; 396 enterprises were seriously affected and their factory premises and main equipment were basically damaged. By 27 July, 81 percent of the affected enterprises had wholly or partially restored production and 221 of them had reached the level of production before the floods. [HK120500 Chengdu Sichuan Provincial Service in Mandarin 2300 GMT 2 Aug 81]

BRIEFS

NONPRODUCTION INVESTMENTS--Beijing, 29 Jul (XINHUA)--Investment in nonproduction projects in the first half of this year remained the same as the corresponding 1980 period though China greatly curbed the scale of capital construction this year, according to the State Capital Construction Commission. Between January and June 1981, investment in workers' housing was 3,000 million yuan, a slight increase over the same period of 1980. The proportion of housing investment to total capital construction investment rose from 18.5 percent during the first half of 1980 to 23.6 percent in the 1981 January-June period. Construction of 74.45 million square meters of housing was started in the period, and 10.89 million square meters of floor space were completed, the same figures as the 1980 period. The state spent more than 800 million yuan on urban public utilities. A total of 259 cold stores are now under construction, and 36 were completed in the first 6 months of this year. [Beijing XINHUA in English 0715 GMT 29 Jul 81]

JILIN RURAL HOUSING--Changchun, 24 Jul (XINHUA)--To expedite rural housing construction, Jilin Province recently appropriated 1,000 dun of steel, 10,000 dun of cement, 3,000 cubic meters of timber and 40,000 cases of glass panes from surplus materials of capital construction projects. To support rural housing, the provincial construction committee and the various prefectural, municipal and county capital construction departments trained more than 1,000 building technicians and designed over 400 layouts of houses for the rural areas. DOMESTIC TRADE

BRIEFS

GUANGDONG MATERIALS EXCHANGE FAIR--Recently, a materials exchange fair was held in Huaiji County by 11 counties in mountainous areas in the border regions of Guangdong, Guangxi and Hunan. The total volume of business done in the 5-day fair amounted to 33 million yuan. The 11 counties are Huaiji, Fengkai, Lianshan, Lian, Liannan, Fuchuan, Zhongshan, He, Jianghua, Dao and Jiangyong counties. Early in 1963, they had organized materials exchange activities in their economic zone; and each of the counties would host a materials exchange fair every year by rotation. However, the fair was forced to be suspended for 10 years during the Great Cultural Revolution. It was resumed in 1977. BRIEFS

LIAONING PORT EXPORTS--Dalian, 27 Jul (XINHUA)--Dalian, Liaoning Province, one of the country's biggest ports, handled export goods worth 1,918.3 million U.S. dollars during the first 6 months of this year, a port spokesman said today. He said the amount represents a 3.1 percent increase over the same period last year. During the January-June period, the spokesman said, an increase was registered in exports to Japan, Hong Kong and Macao. Exports to the United States were down because of reduction in crude oil exports. Goods to Japan totalled 1,227.4 million U.S. dollars, 16.5 percent more than that of the same period last year, and 64 percent of the total export volume, the spokesman said. The export of shelled peanuts, gunnysacks, gym shoes and aluminum alloy ingots increased three to seven times. According to the spokesman, goods from Dalian went to more than 140 countries and regions, including Britain, Japan, Romania, Sweden, the United States, and Hong Kong and Macao. [OW031441 Beijing XINHUA in English 0222 GMT 28 Jul 81]

TRANSPORTATION

BRIEFS

LIAONING RAILWAY REPAIRS--The task for rushing to repair tracks damaged by floods on the railway line linking Shenyang and Dalian has been completed. By 1900 on 4 August, both Shenyang and Dalian railway stations had restored service. [SK072304 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 5 Aug 81]

SICHUAN COMMUNICATIONS, TRANSPORT--Since the beginning of this year, the staff and workers of Sichuan's communications and transport departments have actively strived to increase production, practice economy, increase income and economize expenditures. Under the conditions of the short supply of fuels and insufficient task assignments, they overfulfilled in the first 6 months the volume of freight transport, the rotational volume of freight transport, the volume of passenger transport, the rotational volume of passenger transport and realized a profit of 32.94 million yuan, fulfilling the task to deliver profit to the state. [HK120500 Chengdu Sichuan Provincial Service in Mandarin 2300 GMT 11 Jul 81]

TRANS-TIANSHAN-MOUNTAINS HIGHWAY--Urumqi, 2 Aug (XINHUA)--Officers and men have completed a 560-kilometer-long highway across the Tianshan Mountains, the first of its kind in China. Asphalt is being poured to surface the new highway, and the last tunnel is still being driven. The project is undertaken by a unit of the construction corps of the people's liberation army to improve the road transport between the northern and southern parts of Xinjiang separated by the Tianshan Mountains. Usually it takes 4 days to travel by truck taking a roundabout route from Urumqi or from the Ili Valley. The time will be greatly cut after the new road is opened to traffic, and the dense forests, the vast pastures and the buried deposits in the area will be better utilized. NATIONAL SYMPOSIUM HELD ON MINERAL ENVIRONMENTAL RADIATION

Beijing GUANGMING RIBAO in Chinese 13 Jul 81 p 1

/Article by GUANGMING RIBAO correspondents Lin Yushu /2621 3768 2885/ and Zhou Zhumou /0719 3137 6180/: "Gratifying Progress in Mineral Environmental Radiation Research in China--First National Academic Discussion on Mineral Environmental Radiation Held in Beijing"/

/Text/ Gratifying progress has been made in mineral environmental radiation research in China, and a scientific and technological contingent of a fairly high level is now in existence. For many years this contingent has undertaken a great deal of scientific research on uranium mines and associated radioactive minerals with considerable success.

First, research on the methods of, and equipment for, ventilation and radon reduction in uranium and other types of mines in various aspects. This has not only solved the problem of ventilation, radon reduction and radioactive pollution control in these mines, but has also produced many comprehensive measures for air circulation, airtightness and the control of radon separation suitable for the specific conditions in China. Particularly noteworthy is the method of pressurized air circulation whereby radon density is reduced by more than 90 percent when the wind force is reduced by two-thirds.

Second, new methods of and equipment for radon measurement. The balloon method for speedy measurement is now in popular use, while the activated charcoal filter paper, the portable KF-601 radon-thorium instruments and other similar equipment are well received because of their speed, accuracy and simplicity.

Third, the production of material for protective layers against radon. After extensive laboratory tests and on-the-spot investigations, the workers engaged in mineral environmental radiation successfully manufactured a new type of antiradon plastic in 1970. Popular use of this plastic has shown that it is 83 percent effective in checking the diffusion of radon gas.

Fourth, some new breakthroughs in the study of occupational diseases from mineral radiation. In the spirit of cooperation, scientific workers have conducted thorough investigations of the causes of occupational diseases among miners and pointed out the harmful effects of radon and arsenic on the human body. Their views are of great practical significance and theoretical value.

The first national academic discussion on mineral environmental radiation was held in Beijing from 29 June to 5 July to sum up the experiences and to promote future work, during which 110 scientific and technological workers submitted 103 papers. Wang Ganchang [3769 3227 2490], head of the Special Group for the Study of Controlled Nuclear Fusion and vice minister of the Second Ministry of Machine Building; and Su Hua, vice minister of the Second Ministry of Machine Building, spoke at the meeting.

PRC JOURNAL ON ORIGIN, DEVELOPMENT OF CORPORATIONS

HK220651 Beijing JINGJI GUANLI in Chinese No 6, 15 Jun 81 pp 48-50, 55

[Article by Yu Xingmin [0151 2450 3046], Guan Bai [7070 4101], and Sun Zhibo [1327 2535 6886]: "Origin and Development of Experimentally Run Corporations of Enterprises Nature in Tianjin"--note passages within slantlines denote boldface type]

[Text] The reform of the economic management system is a matter of prime importance concerning the success or failure of the four modernizations, and concerning which, no matter whether in theory or in practice many subjects are awaiting exploration. In the process of economic readjustment, with the expansion of enterprise autonomy, how economic integration is to be promoted and corporations of an enterprise nature are to be set up constitutes a new problem worthy of immediate investigation. In the following, we present our preliminary viewpoints regarding some aspects of this problem in connection with Tianjin.

I

During the 30 odd years since the founding of the PRC, corporations of various types in their capacity as a form of organization have played important roles in strengthening economic management and developing production. Just after liberation, there were three types of corporations in Tianjin: corporations of a bureaucrat-comprador nature such as the China Textile Corporation, corporations using foreign capital such as the Yizhong Tobacco Company, and local privately owned corporations such as the Renli Company (with affiliated factories manufacturing woolen textile products, carpets, egg powder, and so on). These corporations made up the industrial foundation of Tianjin during the early period after liberation. With the advent of the socialist transformation of private industry and commerce, and the readjustment and reorganization imposed on industries by the state, more than 30 corporations of an administrative nature were set up in 1956 and instituted as representative organizations of the municipal government. In 1958, the corporations were delegated to various districts. As a consequence, the channels for cooperation were upset and thrown into disorder, and the function of the corporations underwent changes. In the early 1960's, a number of cities had the experience of setting up trial "trusts" of various kinds. Specialized "trusts" of Tianjin covering the field of machine tool instruments, papermaking, dyes, plastics, and so on, made helpful contributions to economic restoration and development. It is understandable that due to lack of experience the trial undertakings of such trusts could not but give rise to certain problems. However, in the "Great Cultural Revolution," they were all smashed to pieces without discrimination. From 1970 onward, the corporations were again restored one by one. It should be mentioned in particular that after 1978 with industrial readjustments and management reforms under way, more than 80 corporations of an administrative nature were organized in the industry and communications sector. As indicated by the history of ups and downs of corporations in Tianjin, every downfall of the corporations brought passiveness and losses to economic management and production development. In contrast to this, each rehabilitation of the corporations stood out as crucial steps for economic readjustment and reform, bringing economic rehabilitation and development. It was notable that industries which persisted in practicing management methods of a corporate nature enjoyed faster development and better economic effects. The Tianjin Papermaking Corporation has been operating on "trust"-based management methods since 1965 with the main features as follows:

//First practice specialized production.// Production of the original plants was reorganized. The original 17 plants were regrouped into 24. Readjustments were made in respect to product varieties in the light of the production technology of each plant, and each plant as well as each machine was assigned a specialized task in terms of product variety. This production specialization ensured extensive use of new technology and skills and the continuous improvement of product quality.

//Second, practice complete sets within trades.// One complete set concerns the supply of pulp for papermaking. Another complete set concerns the supply of unprocessed paper for paper processing. Over a long period of time, the thick-paste pulp produced by the Tianjin Paper Factory, the cotton pulp produced by the Fifth Tianjin Paper Factory, and the conglomerate wood-chip pulp produced by the Jinzhong Paper Factory have been carefully integrated into full sets for the 24 machines of the 15 production plants. This has guaranteed the constant development of pulp, unprocessed paper and finished paper of the group.

//Third, practice unified control over part of the goods and materials supplies.// Since 1965, papermaking companies have set up purchase and supply stations for the whole trade. Unified allocation of major raw materials such as pulp and caustic soda for papermaking have been made according to the needs of the companies, and delivery to the factory of the needed materials has been guaranteed. Rational allocation of the three major materials needed for maintenance and technological adjustments has also been made by the companies according to approved programs. With respect to scrap paper needed by some of the factories, purchase, classification, and supply have been made by the companies on a collective basis. These measures not only lessen the amount of funds tied up, but also facilitate adjustments between surplus and deficit. This ensured the proper production of the factories.

//Fourth, centralize allocation of special-purpose funds according to set ratios.// Ever since the "trust"-style management was run on a trial basis, the corporation has persisted in centralized allocation of the major overhaul funds and depreciation reserves. The corporation keeps half of the major overhaul funds, and the factories keep the other half. As for depreciation reserves, the corporation keeps 30 to 50 percent. For the rest, part of it is turned over to the state, and part is kept by the factories. In the past 15 years, the corporation has rebuilt the pulp-making facilities and 18 papermaking machines of 6 factories by making combined use of the funds it had managed to pool together and other investments. Worthy of particular mention is the conversion of 7 round-net papermaking machines into short and long-net machines, which raise productivity by 20 percent. From 1965 to 1979, the value of fixed assets of the whole trade was increased by 70 million yuan, 40 percent of which was realized through the centralized major overhaul funds and depreciation reserves.

In the last 2 years, Tianjin Municipality experimented with corporations of an enterprise nature producing colored knitted goods and carpets. The results achieved are quite notable. The following are the main features:

//First, corporations practice unified planning and rational division of work according to the principle of production specialization, change from small-batch production to large-batch production, reorganize "large and complete" and "small and complete" enterprises, improve product quality, production reduce costs and enhance competitiveness on domestic and international market.// The Tianjin Colored Knitted Goods Corporation has 12 "small and complete" knitting factories. In the past, one variety of products was produced by several factories; at the same time a single factory produced several varieties of products. This not only brought disorder to management, but also degraded the quality of the products as well as hampered production development. With the setting up of trial corporations of an enterprise nature, based on the principle of "enterprise product variety must be specialized, trade product variety must be complete," and in accordance with the conditions of equipment, technology, management experience, and development orientation of the various corporations, the 17 groups of products of the trade were rationally reorganized and their production reassigned. Basically speaking, as a result of this, each factory has achieved specialization and each has given play to its advantages as well as avoided irrational duplicate production and blind development. In consequence, obvious economic effects have been achieved. With the improvement of product quality, the medium and high-grade goods have increased. With the enhancement of productivity, the weaving efficiency of the whole trade has been improved by 3 percent, and output value by more than 3 million yuan. With the increase in profits and with the reassignment of production tasks, of the 420 white-fabric weaving machines of the whole trade, 240 were converted into colored-fabric weaving machines, increasing profits by 2.1 million yuan. Thereby, the enterprises have changed in appearance, and the fundamental operation and management work have been much improved.

//Second, the centralized allocation by the corporation of part of the production funds and depreciation reserves has accelerated technological restructuring and patching up of the whole trade. This has enhanced the capability in carrying out cooperation and matching up complete sets of equipment, giving full play to production capacity and impetus to the development of production of the whole trade.// At present, many medium and small sized enterprises are facing the problem of outdated equipment, low productivity, poor capability in matching up complete sets of equipment, insufficient production funds scattered among the plants, inability to form a "fist," and thereby inability to achieve anything of importance. By centralizing allocation of production funds, 50 percent of the major overhaul funds and 70 percent of the replacement and restructuring funds, the Tianjin Colored Weaving Corporation combined the three. This year and the following year, the corporation plans to undertake technological restructuring of 10 of its factories. Weaving machines are expected to increase to 1,000, and yarn-dying capacity is expected to increase from 60 pieces per day at present to 100 pieces. By 1981, output value will have doubled in comparison with 1978.

//Third, through redistribution of prices or profits within the corporation, the problem of disparity of joy and hardship due to objective factors such as prices, tax rate, and so on, has been rationally resolved.// While the Tianjin Colored Weaving Corporation was readjusting the product assignments of its factories, it was found that due to price factors, profit differed by too wide a margin among different products, and all its factories scrambled for the high-grade goods with larger profits. Since the implementation of the measure of profit redistribution, which ensured that the staff and workers of the respective factories basically got the same reward for the same amount of labor input, the disparity of joy and hardship brought about by objective factors has been removed, and the division of work by specialization successfully promoted.

//Fourth, since the revamping of the corporation along enterprise lines, emphasis has been put on using economic means to manage the enterprise, and noticeable results have been achieved.// The Tianjin Colored Weaving Corporation has two spinning factories, which supply the yarn needed by its 12 factories. In the past, due to the failure to deliver goods of the specified quality and within the specified time on the part of the dying factory, the production of the weaving factories was hampered. Meanwhile, due to the lack of rigorous planning on the part of the weaving factories, dying work for the items that had not been supplied was often demanded, thus disrupting the normal production of the dying factory. The contradictions on both sides could not be resolved. Since the trial running of the corporation in the manner of an enterprise, the system of business contracts has been promoted. It is stipulated that any party in violation of the contract shall pay a penalty and receive a smaller bonus for its staff and workers. With the adoption of economic means like this, the sense of economic responsibility has been enhanced on both sides, the balance and linking-up of work assignments have been guaranteed, and the quality and production efficiency of the products have been improved. As a result, the turnover of capital has been accelerated, and the development of production promoted.

In short, facts from history and reality tell us that the promotion of economic integration of various forms and the establishment of corporations of an enterprise nature are actions of great vitality.

(II)

In view of the experiences and lessons of Tianjin, the following problems must be studied earnestly and resolved in the event of organizing corporations of an enterprise nature or transforming some existing corporations of an administrative nature into corporations of an enterprise nature:

//First, in setting up corporations of an enterprise nature, the principle of combining voluntary and mutually beneficial integration from bottom to top with guidance and promotion from top to bottom must be upheld.//

In business operation, the economic integration of dispersed but correlated enterprises is much superior to dispersed and independent enterprises. However, this superiority is not comprehended at the beginning, and it takes some time to run through the course of recognition and practice. It is only after experimentation and comparison that a cognizance of the superiority of integration by the grass-roots enterprises can be gained, the demand for integration be formed, and thereby actions be readily put into effect. At present, most of the corporations in Tianjin are of the nature of administrative organizations. In the trial operation of corporations of an enterprise nature, that is, in the process of transition from corporations of an administrative nature to those of an enterprise nature, difficulties and problems of various sorts have been encountered. For these difficulties and problems encountered in the process of development, by taking a positive attitude and adopting effective measures, some corporations have found fairly good solutions and have made encouraging progress in striding forward to becoming enterprise-style corporations. In these cases, repeated consultation from bottom to top and from top to bottom and the correct compromising of interests so as to make economic integration the voluntary action of the grass-roots enterprises, are very important factors. Meanwhile, those enterprises that are reluctant to participate for the time being should be allowed to stay independent, and be allowed either to set up general factories or to look for cooperative partners of their own choice and to engage in competition with the integrated corporations.

//Second, at the very outset of the establishment of corporations of an enterprise nature, the utmost efforts should be made to delegate power to the basic level. The corporation must do its best to serve the basic level units in order to give full play to production potentials.//

In setting up corporations of an enterprise nature, how should authority be delegated? This is a question that must be prudently dealt with. At present, due to our poor management, some of our comrades are still accustomed to managing economics by administrative methods. Consequently, at the outset, too much emphasis is given to centralization of authority, and there is a tendency for the corporation to be transformed from an institution with authority concentrated in its superior controlling organs to an institution with authority concentrated in itself, and the economic segregation of geographical regions may only be replaced by the monopoly of corporations. In fact, if production is organized according to the law of production techniques, the enterprises are best qualified to make comments, when problems arise. Quite often, the superior governing organs are less sensitive to recognizing problems, nor do they provide timely solutions for such problems as do the enterprises, or the staff and workers of the enterprises. Therefore, it is of paramount importance to motivate the initiative of the enterprises and their staff and workers and to confer authority on them as well as responsibility. The corporations should take facilitating production, making things easier for the basic level units and providing better service as their topmost tasks. In accordance with the actual needs and their own capabilities, the corporations should take into their hands in a unified way the matters that the enterprises find very hard to deal with and problems that the corporations cannot solve, and should show the enterprises the benefits in a concrete way in order that full play can be given to production potential.

//Third, corporations of an enterprise nature should be set up along diversified lines.//

On account of the complexity of social production and the diverse forms of specialized cooperation, diversified patterns should be adopted for the establishment of corporations of an enterprise nature, and practices such as "cutting with one knife" should not be allowed. Corporations of an enterprise nature being run on a trial basis and those units preparing to be transformed into corporations of an enterprise nature in Tianjin at present, can be divided into the following categories: 1) specialized corporations composed of plants with similar production techniques and basically similar varieties of products; 2) furniture corporations with emphasis on production operations (one such corporation taking the form of "compensation trade," has set up its lumber supply base in the forest region of the northeast, and contracted sales relations with 88 commercial departments of 17 provinces and municipalities, thus improving sales methods and better balancing market supply and demand); 3) cases such as the carpet corporation that has broken the boundary of trades, bypassed the limits of the ownership system, and set up an industrial and agricultural combine containing both the systems of ownership by the whole people and collective ownership (there are 11 plants operating under this corporation, 9 of which are entities of a collective nature, and 4 of which are agroindustrial enterprises with manufacturing points in rural areas employing a total labor force of 15,000 workers engaged in processing and assembly); 4) loosely organized economic combines such as apparel corporations. Despite the fact that these corporations have just begun their trial operation, and have taken form in an embryonic stage, they have all shown the superiority of economic integration and yielded fairly good economic results.

//Fourth, attention must be paid to economic rationality and economic efficiency in setting up corporations of an enterprise nature.//

Striving for good economic results is the starting point as well as the end result of reorganization and integration. The Tianjin Colored Weaving Corporation has better performance and more noticeable economic efficiency. Since its trial operation as a corporation of an enterprise nature, the value of its industrial output in 1979 increased by 26.3 percent compared with 1978, and that for the first half of 1980 increased by 29.5 percent compared with the same period in 1979. As for profits, its score for 1979 increased by 28.7 percent in comparison with 1978, and an increment of 49.5 percent was made in the first half of 1980 as compared with the same period of 1979. In the meantime, noticeable improvements have been made in labor productivity, exchange earnings in export, and product quality.

By economic rationality, we mean close economic contacts and voluntary integration of those entities that are in need of cooperation. No integration should be made just for the sake of integration itself, putting together through the medium of administrative means enterprises that are not economically related and for which cooperation is irrelevant. When Tianjin Municipality first carried out trial operation of corporations of an enterprise nature, negligible results were achieved in cases where match factories, cosmetics factories and cigarette factories were put together.

//Fifth, the relations among the interests of central government, local government, enterprise, and staff and workers must be correctly handled.//

Since the enterprises were set up at different times and their product lines differ, they are very different in technology and equipment, and many contradictions have been found between product prices and tax rate systems at present. In addition to this, the employment of staff and workers is effected through centralized placement by the state. These objective factors give rise to the unduly large discrepancies among profits made by different enterprises. This evidently again gives rise to artificial inequity in gains and losses. After implementation of unified earmarking of profits and redistribution of profits in accordance with business performance, the Tianjin Colored Weaving Corporation has achieved the heartening result of more revenue for the state, a larger profit share for the enterprises, and more income for the staff and workers. This provides the physical foundation for consolidating and developing unification.

//Sixth, with the establishment of corporations of an enterprise nature, the broad ranks of cadres must adapt themselves to the changing new situation and organizationally guarantee the healthy development of the corporation.//

After the corporations are converted into economic organizations, economic means must be adopted and economic responsibilities must be undertaken. This demands more rigorous requirements from the managing cadres, both in their ideological style and form of management. These managing cadres must be in the prime of life, of enterprising spirit and with a strong sense of responsibility. In addition, they must improve themselves and acquire technological and management expertise. All this must be done so as to gain the initiative in directing production and operation. For the purpose of adapting to the requirements of the enterprization process, last year the Tianjin Colored Weaving Corporation demoted 16 cadres who were not professionals with technical and management knowledge from leading posts, and in their place commissioned 17 young and energetic professionals with technological and management expertise. In the same year, the corporation also appointed five secretaries of party branches of the corporation, who are in the prime of life and who had worked their way up from the professional ranks, and entrusted them with the post of superintendents; in the meantime, 16 engineers and 3 accountants were promoted in order to reinforce the foremost front of production. By virtue of the posts they were assigned to, they were given due authority and responsibility. Through readjustment, among the 63 leading cadres at the basic level, 62 percent of them are professionals. Thus guaranteeing the corporation's realization of enterprization, organizationally speaking.

PEARL RIVER ESTUARY OILFIELD

'WEN WEI PO' Article

HK210321 Hong Kong WEN WEI PO in Chinese 20 Aug 81 p 3

[Dispatch from Guangzhou: "Extent of Pearl River Estuary Oilfield Published"]

[Text] The responsible person of the South China Sea Geology Investigation Headquarters of the Geology Ministry answered our journalist's questions about the appraisal of the oil and gas deposits in the Pearl River estuary.

Q. How was the Pearl River estuary basin found?

A. The Pearl River estuary basin was found by the second marine investigation squadron of the Geology Ministry in 1976. This squadron started its comprehensive investigation of the marine geology and global geophysical features of the South China Sea in the early 1970's. After the completion of their investigation of the Gulf of Tonkin, they moved to the marine area to the east of the Leizhou peninsula and Hainan Island in 1974. In 1975 they found a relatively thick deposit, which suggested that a great basin may have been formed there. Through prospecting and making a comprehensive study of the data from various sources for more than a year, the outline of the basin was drawn up in 1976 and a report was written stating the discovery of the Pearl River estuary basin.

Q. How big is the Pearl River estuary basin and what is its exact geographic location?

A. The Pearl River estuary basin includes the Leizhou peninsula and the east part of Hainan Island and the main body [words indistinct] geographically it lies south of Shantou, Shenzhoe and the Wanshan islands and east of the Leizhou peninsula and Hainan Island and includes the stretch of sea surrounded by the Nansha Islands, the Zhongsha Islands and the Dongsha Islands. The total area of the basin is 150,000 square kilometers. It extends mainly parallel to the coastline.

Q. How did you come by the estimate of the prospect of oil and gas in the Pearl River estuary basin?

A. The estimate of the oil and gas deposits is the conclusion of the comprehensive analysis, processing and scientific calculation of the data collected through overall geological and global physical investigation, drilling and experiments. Up to now the extent we have covered in the [word indistinct] for earthquake, gravity, magnetic and depth surveys has totaled 48,870 kilometers. Seven drilling wells have been sunk with a total depth of 17,275 meters. What is more, indications of gas and oil were found in two of the wells. The discovery of the drilling has further confirmed the conclusion of physical prospecting. The objective knowledge of the conditions for the combination of the source bed, oil storage layer and cap rock provides an important base for the estimate of the oil and gas deposits. Marine geologists have made a study of the formation of petroleum in the earth's crust. By processing tens of thousands of scientific data and adopting the chloroform-asphalt method of calculation, they have calculated that there are very heartening prospects for the deposits on the basis of the area of the basin, the thickness of the source bed and the structural conditions for the storage of oil and gas. This deposit is bigger than that of any other oil field discovered so far in our country. This estimate is based on a large amount of scientific data.

Pearl River Oil Prospecting

HK270733 Hong Kong TA KUNG PAO in Chinese 24 Aug 81 p 2

[Special feature by Guangzhou correspondent Wang Chien [3769 0256]: "Prospecting for Oil in the Pearl River Estuary Basin"]

[Text] The prospect of petroleum resources in the Pearl River estuary basin in the South China Sea has been highly rated by authoritative people of the geological and petroleum circles both at home and abroad.

The Pearl River estuary basin is one of the largest sedimentary basins in South China. As a result of the silt carried down by the Pearl River system, the rate of accumulation of organic matter and the depth of underwater sedimentary deposits in this basin are quite impressive. The anticlines in the depths of the ocean could possibly be oil reservoirs. The discovery of such unique geological structures has caused people at home and abroad to view the vast Pearl River estuary basin in a new light.

Discovery of the Pearl River Estuary Basin

Following the gratifying results obtained from the aerial survey carried out in the Gulf of Tonkin in the early part of the 1960's and the systematic survey carried out in the Gulf of Tonkin and the waters around Qiongzhou in the early part of the 1970's, the ocean and geological survey personnel of the Chinese Ministry of Geology in the autumn of 1974 moved their forces to the vast sea area east of Leizhou and Qiongzhou and carried out a large-scale ocean and geophysical survey from the continental shelf of Guangdong to the Dongsha and Xisha archipelagos. At the same time, geologists traveled all over Guangdong and Guangxi and also 35 islands in the Pearl River estuary and 14 islands in the Xisha archipelago to carry out a comprehensive study and survey of the land, ocean and islands.

After 2 years of hard work, this ocean geological survey contingent, which disregarded difficulties and perils and made light of discomfort, mapped out 150,000 square kilometers in the Pearl River estuary basin as an area rich in oil and natural gas resources.

The extent of the Pearl River estuary basin stretches from the waters east of Shantou to the eastern side of the waters west of Hainan Island and to the Dongsha archipelago in the south. It has been scientifically proven that the sea bottom of this vast area formed three major depressions ranging from 50 meters to 1,500 meters in depth.

Basin Formed 40 Million Years Ago

The Pearl River estuary basin is a geological structure formed 40 million years ago, and the combination of structures for creating, preserving and trapping of oil is good. This is the scientific assessment of ocean geologists and surveyors.

As a result of the discovery of the Pearl River estuary basin, in order to speed up the investigation of petroleum and natural gas in the basin, the Chinese Ministry of Geology decided to set up the South China Sea Geological Investigation Command in 1976. At present, it has an ocean geological prospecting contingent of nearly 2,000 men equipped with advanced ocean investigation ships and such new equipment as self-hoisting drilling platforms introduced from abroad.

The South China Sea Geographical Investigation Command has mainly adopted the seismic prospecting method in the carrying out of comprehensive ocean geological investigation. It has geophysical prospecting ships equipped with compressed air cannons and electric spark detonators for creating epicenters.

Epicenters are caused by discharging compressed air cannons at the sea bottom at a pressure of 1,800 pounds per square inch and by electric charges released at a depth of 10 meters under water. Echoes created by the epicenters at the sea bottom are picked up by microphones and recorded on seismographs. By means of the seismographs, the underground formation contours, structures and slopes of the sea bottom can be studied.

The geological structure of the Pearl River estuary basin, formed 40 million years ago, is now clearly understood in the light of modern scientific prospecting. Comprehensive investigation of ocean geological prospecting has at the same time adopted gravity surveys to find out about the density of large rock formations and ascertain whether they are granite, basalt or metamorphic rock. Moreover, magnetic surveys have led to an understanding of the very obscure conditions of the magnetic base.

Based on the enormous amount of information from geological surveys and exploratory drillings carried out in the Pearl River estuary basin since 1977, the South China Sea Geological Investigation Command, by means of experiments and chemical analyses, has verified the discovery of a reasonable distribution of anticlinal structures in the more than 20,000 square kilometers already investigated in the northern part of the Pearl River estuary basin.

The numerous anticlinal structures in the Pearl River estuary basin are like a number of oil reservoirs in the depths of the ocean. Some have already been drille for oil and some have yielded traces of oil gases.

Formation of Petroleum in Pearl River Estuary Basin

Since the formation of the Pearl River estuary basin 40 million years ago, the thickness of sediments deposited and the rapid accumulation of sediments have amazed geologists. These extremely favorable conditions for the formation of petroleum are provided by the Pearl River system.

From the plateaus of Yunnan and Guizhou, the water of the Pearl River system winds its way through mountains and hills. Each year, it actually discharges 300 billion cubic meters of water into the sea. The mud and sand carried down rapidly filled the sunken basin, and the thickest part of the sedimentary deposit is about 11,000 meters deep.

The Pearl River not only discharges an enormous amount of silt into the sea, but it also carries a great deal of plankton of higher and lower orders as well as microorganisms. The enormous amount of organic matter sinking into the sea bottom is rapidly covered up by the sand and mud. In the absence of oxygen, it becomes the principal "source material" of offshore oil.

Authoritative people of the geological and petroleum circles both at home and abroad have already acknowledged the "organic oil theory." Data from the drillings carried out in the Pearl River estuary basin indicate that the Pearl River and the South China Sea have a higher organic matter content, and the quantity of organic matter in the petroleum-forming sedimentary rock at the sea bottom is two to three times higher than that of other basins in general.

Another extremely favorable condition for the formation of petroleum resources in the Pearl River estuary basin is the higher stratigraphic temperature of the steps.

At a depth of 80 meters, the temperature of the sea bottom remains at 19 and 20 degrees centigrade throughout the year, but the temperature in the rock strata more than 2,000 meters deep can be over 100 degrees centigrade. According to the "organic oil theory," the formation of offshore petroleum requires such conditions as temperature, pressure and catalysis, but the most important factor is temperature. In the absence of oxygen, organic matter generally begins to change into petroleum at a temperature of about 70 degrees centigrade. The stratigraphic temperature of the steps in the Pearl River estuary basin, being relatively high, promotes the rapid transformation of organic matter into petroleum. Indeed, it can be described as a veritable breeding ground for offshore petroleum.

Stratified Oil Shales of Moderate Thickness

Filled by billions of tons of silt and an enormous amount of organic matter, the sea bottom of the Pearl River estuary basin is like a dome-shaped layer cake with a petroleum layer, an oil reservoir layer and a cap layer on top of one another.

The South China Sea Geological Investigation Command has drilled seven oil and gas wells in the Wanshan archipelago off the mouth of the Pearl River and the sea area south of the Dangan islands. Findings have verified the existence of layers of sedimentary rock and sandstone scores of meters apart on the sea bottom, and this is the most ideal form of combination. Sedimentary rock is an oil-producing layer and the sandstone is a reservoir layer. On top of the sandstone is another layer of mud stone. It not only seals off the oil bed of the lower layer, but it also supplies petroleum to the upper sandstone layer. The sandstone, like a sponge with pores, is the most ideal breeding ground for offshore petroleum.

The overlapping layers of rock generate a tremendous pressure which forces the petroleum produced in the sedimentary rock layer into the sandstone layer. This is known in geology as a "primary migration." Geologists call the ratio between the petroleum forced out from the sedimentary rock and the residue petroleum the "evaporative coefficient." The bigger the coefficient and the more hydrocarbon compounds expelled, the better will the oil-producing rock formation be able to bring its role into play.

The oil-producing rock formations in the Pearl River estuary basin are stratified and of moderate thickness, and what is more their "evaporative coefficient" is rather high. This is an important factor we cannot overlook in determining whether or not an off-shore oilfield has industrial value for extraction.

Ancient Coral Reef of Dongsha Archipelago

The prominent anticlinal structures in the geological condition of the Pearl River estuary basin have aroused the interest of people of the geological and petroleum circles both at home and abroad.

At the same time, the Pearl River estuary basin has also quite a number of nonanticlinal oil traps such as ancient coral reefs buried under the sea.

In the northern barrier of the Dongsha archipelago and the submerged shoal of Shenhu, the elevated parts of the sea bottom could possibly be ancient buried coral reefs. Over a long geological period, they have grown and sunk and eventually become buried in mud at the bottom of the sea. Their honeycombed pores could well be filled with petroleum.

There are also all kinds of sandbanks such as river mouth sandbanks and river course sandbars in delta areas. These have proved to be natural oil reservoirs at home and abroad. There is a good chance that the sandbanks of the Pearl River delta will also contain oil.

We also must not overlook the oil traps formed by the silt deposited in the Pearl River estuary basin.

New Techniques, High Quality and Speed

In prospecting for petroleum resources in the Pearl River estuary basin, the South China Sea Geological Investigation Command has also adopted a series of the latest testing techniques, such as "stable isotope," "chromatography--mass spectrum" and ultramicroscopic fossils to study the strata, oil-producing rocks and crude oil. The very accurate scientific data has provided the scientific basis for making an optimistic appraisal of the petroleum resources in the Pearl River estuary basin.

For example, a number of anticlincal structures have already been discovered in the Pearl River estuary basin. They are large and in perfect condition. Because structural movements have not been intense, faults are not very prominent. This has enabled the oil beds on the sea bottom to be better preserved.

Furthermore, the South China Sea Geological Investigation Command has already drilled seven oil and gas-producing wells in the Pearl River estuary basin. The crude produced by the number five well is a light oil of fairly good quality. The Guangzhou branch of the China Geological Prospecting Company has sold the information on four of the wells to 21 foreign oil companies headed by Texaco, Exxon, Mobil and Phillips.

The outstanding achievements made by the surveyors of the South China Sea Geological Investigation Command of the Ministry of Geology after several years of efforts in the Pearl River estuary basin can also be considered fast in the history of international offshore oil prospecting.

NATIONAL POLICY AND ISSUES

EXPANSION OF POWER INVESTIGATED

HK240600 Beijing JINGJI GUANLI [ECONOMIC MANAGEMENT] in Chinese No 6, 15 Jun 81 pp 42-43

[Article by the investigation team of the Kunming Textile Mill: "An Investigation of the Expansion of Power of Supply, Production and Marketing in the Kunming Textile Mill"--note passages within slantlines denote boldface type]

[Text] The Kunming Textile Mill is one of the important mills producing cotton yarn and cotton cloth in Yunnan Province. After expanding its power in September 1979 under the prerequisite of fulfilling the state plan, the enterprise had the power to undertake processing with supplied materials and the power to produce part of the products using the raw materials saved and the power to place new products (such as polyester khaki) on trial sale. Being important products having a bearing on the national economy and the people's livelihood, cotton and cotton textiles are subjugated to state monopoly purchase and marketing according to the present state regulations. In these circumstances, how to expand enterprise autonomy in supply, production and marketing has become a problem which needs further study and solution.

I. The Situation of Supply, Production and Marketing

/1) Production plans are subject to unified state assignment./ At present, the production tasks including the total output and the whole variety, specifications and quantity of cotton yarn and cotton cloth are targets mandatory in nature passed down to the enterprise by the Provincial Textile Industrial Company. The enterprise is basically not authorized to work out any complementary plans in accordance with the market demands.

/2) Raw cotton is subject to unified state distribution./ The specification and quantity of the cotton needed by the production of the mill is checked and ratified by the Provincial Textile Industrial Company and directly organized and supplied by the Provincial Tobacco, Cotton and Hemp Company. Cotton is all supplied by the state. The mill is only in a position to ask for whatever grade of cotton it is supplied with and sets prices in the light of the prices given, hence production according to supply.

/3) Products are subject to unified state purchase and marketing./ Part of the products that should be marked by the cities is purchased by the commercial departments in a unified way. Semifinished products are allocated and sold to various textile units according to the state plan. The enterprise has no power to market them. If a plant plans on setting up a municipal branch retail outlet to place its new products on trial sale, it applies to the Municipal Industry and Commerce Administration and Management Bureau for a business permit. The Municipal Industry and Commerce Bureau refers it to the commercial departments concerned for ratification, but the provincial commerce department maintains that it would be enough to have the agreement of the urban commerce bureau. But the urban first commercial bureau regarded that "it is not necessary for the Kunming Textile Mill to set up its own municipal retail outlets since it is located in the municipal district."

/4) Product prices are subject to unified state determination, no downward adjustment of price is allowed, still less an upward one according to changes in production cost or market supply and demand./

II. The Problems Existing at Present

At the present time, the production of raw cotton in our country is insufficient. We need to import some cotton from abroad. It is necessary for the state to monopolize the purchase and marketing of cotton and cotton textiles in order to ensure the basic needs of the livelihood of the people. However, there are some defects in it. They are mainly:

/1) Plans are excessively and rigidly controlled, the enterprise has become mainly a unit which carries out plans of a directive nature without any power to make its own decisions./ This leads the enterprise to a situation in which when the materials are used up, the enterprise asks the departments above for materials, instead of trying its best to open up new sources of materials; in production, it follows the prescribed order and acts according to the plans of a directive nature; if the products within the plans do not suit social needs, it produces them regardless; as long as it increases production, its revenue is increased. These practices are detrimental to the mobilization of the enterprises' enthusiasm for studying on their own initiative how to raise product quality, improve technology and skills, increase the variety of product design, size and color, reduce consumption and cost and improve labor productivity. In this way, the enterprises live off the state plan, eking out peaceful existence.

/2) The present price and tax systems are detrimental to the readjustment of the product structure of the enterprises./ The present price parities are irrational. Some goods whose supply exceeds demand are overpriced affording big profits and some goods for which supply falls short of demand are insufficiently priced with little profit. After practicing profitsharing, in order to obtain more sharing of profits, enterprises very often seek the production of goods whicy are in excessive supply with big profits and are unwilling to produce goods which were in short supply with little profits, with the result that the production of goods for which supply exceeds demand cannot be reduced and that of goods for which supply falls short of demand cannot be increased.

/3) There are breaches in the supply of raw materials./ The state unified distribution and planned allocation, the mandatory production targets assigned by the higher departments to the lower units and the responsible departments' raising of the quotas at each level cause the constant emergence of breaches between the production plans and supply of materials. Sometimes, the enterprise cannot take delivery of the goods for which it has paid. The supply of cotton of a certain graded length cannot be supplied at a fixed time, the enterprises have to use thick yarn with low cotton spinning, resulting in a decrease in product quality, or they have to use thin yarn with high graded cotton spinning, resulting in an increase in production cost.

/4) The state monopoly for marketing the products, the slight influence of market mechanism over enterprises and the lack of external pressure on enterprises to be competitive are detrimental to the promotion of improving product quality and increasing the variety of product design, size and color./ Meanwhile, the unitary circulation channels, the unified purchase of products by the commercial departments, the redundant circulation links, the lack of direct relations between the production units and the consumers, the enterprises' poor understanding of the fluctuations in market demand and the unmarketable variety of product design, size and color cause the overstocking of products.

III. Some Proposals

Cotton and cotton cloth are important state materials which have a vital impact on the national economy and the livelihood of the people. At present the production of cotton, cotton cloth and knitted cotton goods is far from satisfying the needs of the livelihood of the people. For this reason, the policy of state monopoly of purchase and marketing has to be carried out for comparatively long periods of time. Regarding the matters of how to turn enterprises into relatively independent commodity producers, how to revitalize enterprises and help raise the national economic effect and how to define the expansion of the power of supply, production and marketing of the enterprises under the system of the state monopoly of purchase and marketing, on the basis of our investigation and the opinions of the enterprises and the departments concerned, we have made the following tentative plans and proposals:

/1. On the question of enterprises' autonomy over production plans./

Concerning the total output quotas for cotton yarn and cotton cloth, and some of the main products which are needed badly on the market and are in short demand (such as 23x21 plain cloth and 23x21 gauze), the state should assign plans of a directive nature. With regard to other products, under the prerequisite of not exceeding the total output quotas, enterprises should be allowed to work out production plans according to the contracts for purchase and marketing signed by both sides, the enterprises and the commercial departments. In this way, the enterprises' whole production plans consisting of the state plans of a directive nature and the enterprise-formulated plans enable the enterprises to have part of the power to work out production plans, and help the enterprises to better adapt their products to market demands.

With the prerequisite that they fulfill the state plans of a directive nature and the purchase and marketing contracts, enterprises should be authorized to undertake processing with the materials supplied or cooperation tasks and change the situation in which enterprises are wholly dependent on the state for their supply of raw materials. Under the condition of not changing the orientation of products, enterprises should be authorized to produce marketable products with the raw materials saved in the process of production.

/2. On the problem of the supply of raw cotton/

With regard to the products within the plan of a directive nature, the plan-assigning departments should ensure the supply of raw materials and leave no breaches. Under the guidance of state planning, the contracts for arranging production plans according to market conditions signed by the enterprises and the departments concerned should be submitted to the state, and the departments concerned should guarantee the supply after checking and ratifying the volume of supply of materials in the light of the contracts. In accordance with the reported plans for trial-production of new products by the enterprises, the state should allocate a certain percentage of cotton needed in trial-production of new products, based on their progress. To reduce circulation links and cut down expenses, the mill should be directly supplied with raw cotton.

/3. On the problem of power over sales./

The enterprises maintain that they should have the power to place 5 percent of the new products on trial sale and to sell 2 percent of the marketable goods through their own channels. The provincial knitted textile center has suggested that acting upon the State Council's Document No 170 (80), enterprises should be permitted to sell 5 percent of the new products on a trial basis but it does not agree upon the trial sale of 2 percent of all marketable goods. We are of the opinion that in order to enlarge circulation channels, help enterprises to understand the market conditions of supply and demand, concurrently avoid competition in selling marketable goods and in getting a bigger share of industrial and commercial profits, enterprises should have the power to place new products on trial sale for 1 year, and the commercial departments should have the power to purchase according to the principle of priority. If the commercial departments do not purchase the goods produced with the materials saved by the enterprises, the enterprises are allowed to market them through their own channels both wholesale and retail, but their wholesale prices should be in keeping with the allocated and retail prices of the local commercial departments. The enterprises should demand and collect cloth coupons in this respect according to the rules and regulations issued by the Ministry of Commerce, and collect and hand them over to the departments concerned. For detailed measures, enterprises are justified in organizing sales exhibitions, setting up outlets for sales through their own channels, through industrial and commercial enterprises or on a commission basis.

/4. The problem of prices and taxation./

At present, the prices of cotton textiles brook no fluctuation or readjustment. The price parities of the various products of these enterprises are irrational. This has lead to a situation in which the prices of marketable goods are on the low side and their profits are limited while those of unmarketable goods are on the high side but their profits are enormous. Calculated in terms of the interest rate of production cost, the cost prices of some new products (polyester khaki) are not expensive but they are overpriced, and their absolute profit volume is relatively big. Under these circumstances, in order to correctly handle the economic interests between the state and the enterprises and arouse the enthusiasm of the enterprises for producing marketable goods, the following measures are suggested:

1) The enterprises should ensure the fulfillment of the state's plans of a directive nature. In case they fail to fulfill the plans due to managerial reasons, a fine should be imposed on enterprises for failing to fulfill particular varieties of designs and output and the fine should be deducted from the profits retained by the enterprises after handing over income tax.

2) As for products with a low price and minimal profits, but which are urgently required on the market, an otuput base should be defined in the light of their historical production levels. The whole or part of the portion in excess of the plan should be exempted from income tax but not from industrial or commercial tax.

3) Levy a tax on products. Enterprises are permitted to place their new products (polyester khaki) on trial sale for 1 year and are in a position to retain all the profits for their own disposal. After a year of trial sales, a tax should be levied on the new products and should be paid before handing in income tax to the higher level. The definition of the tax rate levied on products should tally with the principle that the state should get more, the enterprise should get less; the enterprise should get more than it would get for producing ordinary old products.

/5. It is good for the textile trade to take the company as the unit in expanding autonomy./

The level of the socialization of production of the provincial textile trade which has an elaborate division of labor and cooperation is relatively high. Even though the expansion of autonomy in a single textile enterprise enlivens an enterprise, it can hardly tally with the macroeconomic demands and hardly reach the goal of producing more rich and varied textile goods, and is detrimental to regulating the relations of economic interests between the state and the enterprises and among the enterprises themselves. Now that provincial and municipal textile industrial companies have been established, the system of two-tier companies should be solved as soon as possible so as to create conditions for expanding the autonomy of the whole company.

ECONOMIC JOURNAL ON TRADE ASSOCIATIONS

HK010809 Beijing JINGJI GUANLI [ECONOMIC MANAGEMENT] in Chinese No 6, 15 Jun 81
pp 56-58, 63

[Article by Li Jing of the Hunan Provincial Academy of Social Sciences [2621 7234] and Du Xiufeng of the Hunan Provincial Machine Building Committee [2629 4403 1596]: "Discussion on the Question of Establishing a Machine Building Industry Trade Association"]

[Text] The machine building industry bears the responsibility of providing technological equipment to various agencies that are involved in the national defense buildup or economic development. It also has the function of supplying durable consumer goods for the people's livelihood. It is strongly connected with modernization of the entire industry. The level of national economic development depends, to a large extent, on the level of development of the machine building industry. The central authorities have determined that the readjustment of the machine building industry is the focal point of the entire industrial development. This is a very correct decision.

There is mutual cause and effect between the readjustment of the machine building industry and the reform of the machine building industrial management system, with each mutually helping the other. Undoubtedly the readjustment creates the preconditions for reform. Inevitable and feasible reforms will in turn help overcome the barriers of readjustment and promote the penetration of such readjustment. This essay attempts to examine the issue of breaking up the departmental and regional boundaries and setting up trade assocation. Through such it will explore a road for reforming the management of the machine building industry. The following presentation will take up three issues:

1. The Defects of the Existing Management System

The machine building industry has developed considerably since the founding of the state. It now has an enormous establishment, however the existing management system of the machine building industry is a multidepartmental and hierarchical institution. There are the military and civilian sectors in the country. The civilian sector is further divided into two manufacturing systems of general equipment and specialized equipment. The machine building industry is spread out over the 43 departments in this country. In terms of hierarchy, there are the central and regional systems. The regional system is further divided into province (city), district (city), prefecture, commune and village and they all run a machine building industry. This is a confused and fragmented management system. The industry is cut up into thousands of autonomous small "feudal lords" pursuing individual interests. A series of defects has resulted and the fundamental ones are listed below:

(1) It Leads to Considerable Duplicate Production, Duplicate Construction. Over Investment, Great Waste and Poor Economic Effect.

Since the machine building industry has been dissected, a unified market of electrical and mechanical products cannot be established. It is impossible to formulate and execute a set of national regulations for the machine building industry. Each department and region plans its own development according to the needs of each unit. It has therefore resulted in 21 local committees, 28 provinces, municipalities and autonomous regions and 375 enterprises that produce internal combustion engines. Industries such as the automobile, tractor, bearing and electrical industry which are geared up for plentiful production are also highly scattered. Factories that produce bicycles, electric fans and other short-term consumer durables that are in short supply are also booming and blossoming at the same time.

Duplicate production inevitably brings out duplicate construction. Each department and region, in augmenting its own production potential, tries hard to find a good base. The overall view of economic equilibrium is therefore overlooked. The Liling electrical porcelain with productivity excedding 7,000 tons. In recent years, orders from inside and outside the country have amounted to about 6,000 tons, meaning a surplus of productivity. However, the Lujiang electrical porcelain factory 5 kilometers away which produces the same products, received 1 million yuan of investment in 1980 from the department concerned to expand productivity.

Duplicate production and duplicate construction lead to a situation of excessive points but inadequate quantity, low productivity and poor economic effect. Much manpower, money, and resources are wasted.

(2) Duplicate Scientific Research, Duplicate Induction, Dissipation of Technological Power and Low Level Technology.

Each department and region arranges scientific research and introduction of technology according to its particular needs and judgment. This has resulted in a situation in which several departments and regions import seven sets of large-scale component circuit equipment. Apart from the First Ministry of Machine Building, there are another two departments and six provincial cities carrying on negotiations with foreign merchants to import heavy motor vehicles and small saloon cars.

There are altogether 480,000 technicians employed in our nation's machine building industry. The proportion is small but the absolute number is considerable and the potential is enormous. If not for the present dissipation of resources, duplicate production and ineffective mobilization, it would be possible to greatly reduce the gap between us and advanced world technological levels.

(3) The Cutting Off of Horizontal Links Among Enterprises and the Low Level of Specialization and Integration.

The horizontal links among enterprises are hampered by regional and departmental barriers. Therefore when a factory is established, it is geared to be a "self sufficient" all round factory which can cater to both cold and heat treatment work. Among 1,502 machine building industrial enterprises on or above the prefectural level (excluding the military industry), there are only three specialized foundries. The furnaces in the steel smelting works have a total capacity of 256,000 tons. But the actual annual demand does not exceed 35,000 tons. The utilization rate of the equipment is 13.7 percent. In cities like Changsha where industry is fairly concentrated, the commodity ratio of steel smelted products is only 7.3 percent, lower than the national level of 18 percent.

Regions and departments form their own complete systems, and aim at an ever higher rate of self-sufficiency. Enterprises all rush to enhance their capability to manufacture things themselves. Under the interference of some supervising departments, some enterprises even sever the connections for coordinated production, and turn the factory into an all-round factory. For instance, take our country's electric locomotives: they are originally jointly researched by the Tianxian locomotive shop and the Xiangtan electrical machinery plant with the Xiangtan plant producing the electrical machines and electrical control equipment while the Tianxin plant assembles the complete vehicles. Yet later on the department concerned expanded the Tianxin plant to include an electrical machinery workshop and assembly plant, so it could undertake the whole production process.

In conclusion, regional and departmental separation is the greatest barrier to reorganizing and integrating the machine building industry enterprises. Without solving these issues, the machine building industry cannot rationalize its organization and hence it cannot improve the economic effect.

2. Breaking All Barriers Imposed by Regional and Departmental Systems of Ownership and Establishing a Trade Association

The reform of the existing management system is inevitable. Yet there are many views on how to approach reform. We believe that the establishment of a trade association and introducing professional management can effectively break all the regional and departmental barriers. It would also pave the way for a rational organization of the machine building industry.

(1) The Nature and Mission of Trade Associations

A trade association is a voluntarily formed organ for coordinating the production of enterprises producing similar goods. It is not a government agency but has certain executive authority. It is not an economic integrated body but has certain economic functions. It is a semiofficial, semi-people-run, semiexecutive and semieconomic organization. The main functions of a trade association are 1) to follow the state's economic plans, target and policies and, based on market forecasting and trade survey, to form medium and long-term development plans and annual plans for industry. 2) To formulate the policy for technology development plans and technological installations. It has developed technician consulting work and technician training. 3) To formulate a trade standard, including enterprise standards and product standards. 4) To organize and adjust internal coordination. 5) To organize the export and trade products. 6) To organize international competition and criticism within the industry. 7) To report to the government on the conditions of production transacts of the trades and propose relevant requests and recommendations.

The trade association represents all the enterprises in a given trade and can at a suitable time consult and adopt certain technological and economic measures. Under the guidance of the national plan, it can propose a development plan for the trade and certain requisite regulations. Upon approval, these will become the solid expectations of the state toward the inudstry.

The trade association is a managing committee formed by representatives of enterprises producing similar products (including whole machines, parts, foundation parts and some intermediate craftwork). It is responsible for discussion and resolution of fundamental issues and settling work policy. The managing committee has a delicate executive organization responsible for daily routine. The work includes taking on government-assigned topical research, long and medium term planning and help in making diagnoses for industry, and answering inquiries from departments and enterprises. Various regions, departments and enterprises of different institutions can freely join or withdraw. An enterprise producing a wide variety of products can join different rade associations. Any enterprise that joins an association is obliged to comply with the duties of the articles of the association. This includes following the trade association resolutions, reporting to the association on the production level and sharing the expenses for the association's activities.

The trade association will determine its form of organization according to different products. Some may include assembly plants and parts plants in the association, like bicycle factories. Some include the manufacturing plants and main parts factories, while plants making minor parts will join other trade associations, like those for automobiles. Some should strengthen the work of the national associations like the basic parts undertakings. Some should focus on the strengthening of the regional associations like the minting, smelting and heating trades.

(2) Functions of Trade Associations

The organizing of a trade association is conducive to the breaking up of regional and departmental restraints and has an active effect on developing industrial production:

First, it can rationalize the production organization and utilize the active function of the enterprises. This is because trade associations can shed the restrains imposed by departmental segregation and regional blockades. It will start by improving the productivity of industry and follow rational economic principles. It will research into and formulate a development plan and organize coordination and collaboration and fix standards for both the industry and the products. "Pass certificates" will be issued to enterprises that attain a certain standard. "Trade standard certificates" will be issued to commodities that attain a certain standard. The association can also fix a unified price and hence high priced goods of lower quality will be eliminated. The issue of duplicate production will then be easily solved.

Besides, the association can serve as the link between the state and the enterprises. It will make the state's guidance in macroeconomic policies effective toward the microeconomic activities. The state's requirements on certain trades and products will become, through the trade association, the managing principles of the enterprises. The irrational development which is caused by departmental segregation and regional blockades will be avoided.

Second, it is conducive to raising the technological standard. It can consolidate the technological potential of an entire trade, research new products, promote new technology and avoid duplicate research and development as well as mutual segregation. Hence the research and development will be expedited and production standards will be raised. Based on the national and industrial conditions, the association will formulate a policy for renovation plans and technological installation. That is conducive to improving backward production technology. This is an assignment which an ordinary agency cannot cope with, neither is it feasible for a single enterprise or scientific research unit.

Third, it is beneficial to developing professional collaboration. One of the major reasons for the slow progress in professional collaboration is the lack of unified management organization for primary products and specialized craftwork. The state's capital is invested according to the development of all manufactured goods. Many enterprises producing primary goods and craftwork and small factories cannot attain a good standard because of lack of financial resources and technology. The big plants do not trust the help of small plants and they proceed to become "factories capable of everything." Small plants have no option but to manufacture the whole machines, thus becoming "small and complete." If trade associations can be established for smelting, heat treatment, hydraulic pressure items and hermetic sealing, professional collaboration will be promoted.

Fourth, it is beneficial to export: the association is better informed of technological and economic data and more specialized in its business. It is more capable of doing business than foreign trade firms. It is also the unified organization for the external, equivalent to a joint sales center. It may centralize export affairs and avoid internal competition among districts for foreign trade. Besides achieving a consensus, the profits are maintained.

Fifth, it is conducive to enhancing the economic impact of the enterprises. It guarantees that our national industry will keep on an investment-saving, efficient and rewarding road.

(3) Several Issues To Be Solved When Organizing Trade Associations

Trade associations are an innovation. In order to break through regional and departmental boundaries and establish an association, difficulties and resistance from all sides must be met. In organizing a trade association, the following issues have to be solved:

1. It should suitably recognize that the enterprise is a relatively independent producer with the requisite business management autonomy. The enterprise will be liberated from real regional and departmental restraints. Otherwise the resolution of the association will be antagonistic to the interests of the "grandma" enterprises and it will not be thoroughly carried out.

2. It is necessary to manage well the relations between a trade association and a joint venture company. They are not adminsitratively connected, but the joint venture company should be the backbone of the association. Big joint companies should assume leadership of the associations in which the big enterprises should be allowed adequate speech and voting power. It should not resort to repressing the big enterprises to develop small and medium undertakings. Yet is should guard against the control of big enterprises and avoid suffocating competition and create favorable conditions for the small and medium enterprises.

3. It should correctly handle the relations between the national and regional associations. It is more favorable for the associations to be established both at the national and regional levels. A national association should follow after the establishment of associations in the cities. The national associations may be established in Beijing or other industrial cities. For instance associations for bicycles, and sewing machines may be established in Shanghai, associations for machine tools in Shenyang, and so on. It is more advantageous to stick to big enterprises and scientific research centers. As a matter of principle, district associations should be located at provincial or regional economic centers, but it is not necessary for each province to establish one. Associations should not be found everywhere or turned into appendages to administrative machinery. District associations should be subordinated to the national organization. The organizing and admission of district associations has to be done through the national association, forming the base organization. A district should both represent its local interests and keep the overall interest in view. The district association should subordinate its work to the guideline of the national association.

4. It should correctly handle the relations between the association and the administrative machinery. Associations should adhere to the planned guidance of the state and persist in the execution of the state's target, policy, law and order. They should also be placed under the supervision of the state. The government should give serious attention to the suggestions of the associations, especially in the arrangement of production, the distribution of investments, and in fixing prices, taxes, and economic policy. Then the association will better understand the condition and requirements of the trade.

PROMOTION OF RESPONSIBILITY SYSTEM IN FINANCE, TRADE URGED

Experience in Shanxi

Beijing ZHONGGUO CAIMAO BAO in Chinese 25 Jun 81 p 1

[Article by correspondents Zhang Baolong [1728 1405 5693] and Tie Jingkui [1586 4842 7608]: "Finance and Trade Units in Shanxi Promote System of Responsibility for Business Operation"]

[Text] The Shanxi provincial government recently issued a notice calling on finance and trade units at all levels in the province to actively promote the system of responsibility for business operation. In his talk before a report meeting of provincial, prefectural and municipal leaders responsible for finance and trade work, Wu Guantang [2976 0432 3282], secretary of the provincial party committee and vice governor, who relayed the notice, pointed out the need to emancipate the mind and to promote the responsibility system energetically as a type of reform. At the same time, he pointed out that the measures to be adopted must suit local conditions and proceed from realities instead of being carried out as merely a formality or as a ready solution to all problems.

According to incomplete statistics, 220 units of the commercial and grain departments in the cities and countryside of Shanxi Province have tried out various forms of responsibility system in the past 2 years. In April and May this year, vice governors Wu Guangtang and Zhang Tianyi [1728 1131 0044] and six investigation teams of the provincial finance and trade units conducted in-depth investigations in various parts of the province and summed up the typical experiences of the supply and marketing system in Anze County, the food company of Yuci County, the hotel of Datong municipality and some 10 other units practicing the responsibility system. Their methods can be summarized in six different types:

First, responsibility for profits and sharing of surplus profits; second, establishment of work quota, remuneration for fulfillment of quota, reward for above-quota work, and wage deduction for failure to fulfill quota; third, the float-wage sysem under which the regular pay, which is the major portion, is supplemented by a minor portion taken from retained profits; fourth, responsibility for an assigned quota, and remuneration according to sales; fifth, responsibility for loss beyond the approved limit, and such loss will not be made good but loss within the approved limit will be compensated, and the compensation fund will be at the enterprise's disposal; and sixth, responsibility for a set profit quota with rewards for above-quota profits and punishment for failure to fulfill the quota. By closely combining an enterprises' business operation with the responsibility, rights and interests of the workers and staff members, the units practicing the responsibility system have effectively aroused the enthusiasm of the workers and staff members for business operation. Thus their profits have multiplied and their management and service have shown marked improvement. Facts have proved that the system of responsibility for management among finance and trade units is not only necessary but also practicable. It must therefore be unswervingly popularized.

In his talk, We Guangtang pointed out that in promoting the system of responsibility for management among the finance and trade units, the leadership should first of all emancipate the mind and get rid of concern about the difference between finance and trade on the one hand and agriculture on the other and about the complex situation in finance and trade arising from the large number of different departments. They must realize that promoting the system of responsibility is a reform in finance and trade work, and any problem involving policies encountered in the course of such promotion must be promptly solved. Second, the methods and forms used can be flexible and varied, and any of the above six forms can be used. Furthermore, ordinary small and medium-size enterprises can also try out the method of paying tax instead of handing their profits. After paying tax, part of the remaining profits can be used as a bonus fund or for fringe benefits. The enterprises can also practice the system among their workers and staff members in various forms, such as entering into contracts with small groups or even individuals. Contracts for this purpose should be signed, clearly stipulating the main economic targets, duties, and the national policies to be upheld. Third, the measures adopted should suit local conditions and proceed from realities instead of being carried out as a mere formality or as a ready solution to all problems. There should be experiments and summing up of experiences before the gradual popularization of the system. Instead of issuing compulsory orders, they should let the masses conduct democratic discussions before reaching any decision. Fourth, leadership of the organizations should be strengthened, and everyone should cooperate in harmony in solving all problems encountered in the course of experimentation and populatization. Fifth, since the promotion of the responsibility system among finance and trade units involves many other departments and units, including those of urban construction, communications, public health and public security, the departments and units concerned should do everything possible to give the required suppot and assistance.

Gansu Symposium

Beijing ZHONGGUO CAIMAO BAO in Chinese 16 Jul 81 p 1

[Article by correspondent Yang Zhanfeng [2799 2069 6912]: "Responsibility System Is a Necessity for Finance and Trade Departments--Gansu Provincial Symposium on Finance and Trade Work Summed Up Results of Experiments and Called for Emancipation of Mind and Elimination of Fear and Worry"]

[Text] Gansu Province recently held a symposium on finance and trade work to sum up the results of experiments in the system of responsibility for business operation and held that such a system was a necessity for finance and trade departments. It also urged the wiping out of "leftist" ideological influence and the elimination of worry about possible disorder.

More than 200 basic units of the commercial and service trades, supply and marketing cooperatives and food enterprises have tried out the system of business responsibility. The methods used generally took three different forms: First, the workers and staff members as a collective shoulder the responsibility for enterprise management. Second, the enterprise enters into contracts with small groups or the retail department. Sometimes, responsibility for some sectin of the enterprise is transferred to a group which would set up its own store. Third, individual workers or staff members are responsible for the management. The integration of business results with the personal benefit of the workers and staff members aroused their enthusiasm and improved the enterprise's business results, and many enterprises have turned losses into profits.

The participants of the symposium held that in outward appearance at least, the progress of work was not fast enough, because some leading cadres had long been influenced by "leftist" ideas and did not quite understand the necessity and urgent nature of the responsibility system. For example, some leaders thought that "commerce is not the same as agriculture, and therefore, the system of responsibility for business operation, or for profits and losses, cannot be practiced." Others worried about the change in the nature of the enterprises and disorder in the ranks of workers and staff members. To give everyone a better idea, some 10 typical examples of the experiments of the responsibility system were cited in printed form at the symposium. Seeing these vivid examples, those comrades who formerly had misgivings about the system realized that "responsibility for profits, for work, for reduction of loss, and for business results" could work wonders in bringing about vitality and profits. Therefore, they decided that the earlier the change, the quicker will be its effects; and the more drastic the change, the greater will be the benefits.

INDIVIDUAL, INDUSTRIAL, COMMERCIAL UNDERTAKINGS SUPPORTED

Beijing ZHONGGUO CAIMAO BAO in Chinese 4 Jul 81 p 2

[Article by unidentified correspondent: "Individual Industrial and Commercial Undertakings Should Be Strongly Supported in the Supply of Raw Materials--Specific Regulations Given in Joint Notice From General Industrial and Commercial Administration Bureau and Five Other Departments"]

[Text] Households engaged in individual industrial and commercial activities are independent workers living on their own labor. Politically and economically, we should treat these households in the same way as we do units owned by the entire people and by collectives, and all departments should strongly support them in the supply of raw materials and other goods. Some localities at present are discriminating against these households; such an attitude must be changed. This is pointed out in the joint notice of the General State Material Bureau and the General State Labor Bureau issued in accordance with the spirit of comments by the leading comrades of the central government.

The joint notice contains these specific regulations concerning the supply of goods to individual industrial and commercial undertakings in the cities:

1. All raw materials and other goods required by households properly registered in the cities and holding valid licenses for industrial and commercial undertakings should be supplied by the local state-run commercial enterprises, and grain, supply and marketing and material departments according to the approved scope of business. These households should be entitled to the same rate of wholesale prices as given to state- and collective-run units. State-run commercial enterprises, supply and marketing and material departments should set up more wholesale centers according to the scope of division of work and appropriately reduce the minimum wholesale amount for the convenience of these households. As to the goods in short suply for repair service, the material departments should consider the needs of these individual households and accordingly arrange for the timely delivery of goods. As to grain and edible oil, the grain departments should be guided by market demands in supplying to individual catering undertakings the planned quantities in the same way they supply to state- and collective-run catering units. Foodstuff should be supplied against food coupons and edible oil should be rationed according to regulations. Grain and oil outside the plan can be sold at negotiated prices according to local conditions. If the state cannot supply, or fully supply, the required raw materials or other goods, the individual households can buy their own at designated markets after approval by the relevant departments.

2. Households operating retail stalls at country fairs are required to pay nominal rental for the stalls used. Unless approved by the provincial, municipal or autonomous region people's government, no department whatsoever can collect any other fee which would add to the burden of these households.

3. Industrial and commercial administration, commercial, food, supply and marketing, material and labor departments should closely cooperate with one another in providing guidance for the management of these undertakings and in protecting their legitimate business as well as proscribing illegal dealings. All individually run industrial and commercial undertakings enjoy state wholesale prices should sell their goods and pay their taxes strictly in accordance with the state's unified regulations. They are not permitted to carry out illegal transactions, to drive up prices, or to evade the payment of tax.

The joint notice also calls on all localities to once again examine the problems which may crop up in the implementatin of the policy to develop individually run industry and commerce, and to report on the result of their examination.

NATIONAL POLICY AND ISSUES

UNPRECEDENTED INDUSTRIAL GROWTH REPORTED IN HUBEI PROVINCE

Wuhan HUBEI RIBAO in Chinese 13 Jul 81 p 1

[Article by unidentified correspondent: "Industrial Production in Hubei Hit All Time High in First Half of 1981--Production of Light Industrial Goods Needed for People's Daily Life Vigorously Developed in the Course of Economic Readjustment"]

[Text] Since the beginning of this year, the broad masses of cadres, workers and staff members on the industrial and communications front of our province have conscientiously implemented the policy of national economic readjustment and have achieved fairly good results in industrial and communications production through hard work. In the first half of this year, the total industrial output value, compared with that of the same period of 1980, increased by 4.38 percent. This is the best record for the first half of any year in history. In six prefectures and municipalities--Shiyan, Shashi, Xiangfan, Huanggang, Hanning and Yunan--the increase was more than 8 percent. Among the 80 main industrial products, in 52 of them the plan for annual increase has been completed. In passenger and freight traffic by railways, long-distance waterways and local transport, the annual plan has been more than half fulfilled. From January to May, the profits realized by state-run industrial enterprises, as included in the budget, exceeded those of the same period in 1980 by 3.7 percent, and the production cost in comparable terms was reduced by 1.1 percent.

Since the beginning of this year, there has been a sustained growth in light industrial production in our province. In the first half of the year, the ratio of light industrial output value to the total industrial output value of the province was increased from 47.1 to 51.8 percent. Of the 27 main light industrial products included in the provincial statistics, 18, or 66.7 percent, have shown increases over the same period of 1980. Production of the main machinery and power products and consumer goods for daily use such as bicycles, sewing machines, wrist watches, TV sets, radio sets, soap, ceramics, and so forth, has also increased by a fairly wide margin. At the same time, a number of new products, new varieties, new designs and new styles--called the "four news"--were for sale on the market.

In the course of readjustment, heavy industry has gradually turned to serve agriculture, light industry, the people's daily life and export in foreign trade, and the product mix has undergone a gratifying change. The production of various types of pipes and steel bands required in light industry increased by more than 40 percent over the same period of last year, and the production of thin steel plates more than doubled. Upholding the policy of supporting light industry with heavy industry and maintaining heavy industry with light industry, the machinery industry has actively readjusted its orientation of service and directed its efforts to producing machinery and power equipment needed in the people's daily life and providing technical equipment for the textile industry and energy conservation. The scope of these activities has continued to expand along with the growing success. In the first half of the year, the number of varieties of light industrial goods and technical equipment supplied by the machinery industry to light industrial departments increased from 86 in the same period of last year to more than 150. Furthermore, the machinery industry has also arranged for the production of 17 complete sets of equipment required by the light, textile and food industries for technical transformation, including such equipment as required for producing sewing machine panels, carbonated water and beer, for baking bread, and for the recovery and utilization of discarded plastic materials.

LEARNING FROM SHANGHAI

HK010324 Beijing JINGJI GUANLI [ECONOMIC MANAGEMENT] in Chinese No 7, 15 Jul 81 pp 1-13

[Article by Min Gan [7036 3227]: "Learning From Shanghai Is a Practical Way To Promote Economic Effect"—slantlines denote boldface]

[Text] The carrying out of learning from Shanghai activities and other coastal areas in a planned and organized way and the transplantation of their advanced technology and enterprise management and their good experience in reorganizing industry and integration into the hinterland is a most practical and effective way to tap and develop the potential of China's existing enterprises and promote the economic effect.

Ours is a big country with many variants in natural and historical conditions. The level of economic development differs from place to place. There are not only industrially developed cities such as Shanghai and Tianjin but also industrially backward interior areas with relatively poorer lifestyles. Shanghai is China's biggest and oldest industrial base with the most solid foundation, complete industrial sectors and departments, concentrated scientific and technical force, good conditions for internal cooperation and prolonged accumulation of experience. Its level of production, technology, business management and economic effect are much higher than the levels of the hinterland and the national average. At present, the fixed value of Shanghia's industrial fixed assets totals about 6 percent of that of the state, its total industrial output value comprises one-eighth of that of the state and its financial revenue (including enterprises under central jurisdiction) constituted one-sixth of that of the state. The ratio between fixed assets and annual output value is about 1:3 for Shanghai and just 1:1 for the whole nation. The appreciation rate of assets in Shanghai is about 57 percent and that of the 200 cities in the country, on an average, is only 20 percent. The annual frequency of turnover of floating assets of Shanghai is around 6 times while that of the state is 3 times. The utilization rate of energy of the industrial departments of Shanghai is around 33 percent whereas the national average is below 30 percent. The industrial output value of Shanghai is about 30,000 yuan per workers, 1.5 times higher than the national average. The average per-capita GNP of Shanghai is about $1,600 which is 6 times that of the national average level. Jiangsu Province has a relatively developed textile industry, but compared with Shanghai, it still has a long way to go. The fixed assets of the textile trade of Jiangsu Province was 72.4 percent of that of Shanghai in 1979, but compared with Shanghai, its output value was only 60 percent; the foreign exchange earnings through exporting goods was 50 percent that of Shanghai, its profits were 37 percent and the overall level of industry was 40 percent lower than Shanghai. It can be seen that if all the industrial enterprises in the country attain Shanghai's present level, the nation's existing output value and rate of accumulation will double and redouble and the pace of our four modernizations will be greatly accelerated.

To realize the four modernizations, it is necessary to earnestly study advanced foreign technology and scientific management methods. But ours is a developing country with a poor foundation, weak economic base and huge population. Therefore, not every locality and enterprise has the abilities to assimilate and digest the new foreign technology and management methods of the 1970's and 1980's. Viewed from the angle of local industry, the most effective way is to focus the emphasis on learning from Shanghai (and other coastal cities). This is because Shanghai's experience created by assimilating and digesting advanced foreign experience, is concrete and practical, and tallies with China's national condition. Learning from Shanghai enables us to give full play to the superiority of the socialist system, the close relation between the different regions and enterprises, in which the more advanced help the less advanced and the latter learn from the former earnestly and sincerely. Learning from Shanghai is less costly and needs no foreign exchange, so it is more convenient and more beneficial than learning from foreign countries. In the light of their own conditions, Shanghai and other coastal cities can digest, before others, the advanced foreign technology and scientific management methods, and then spread and transplant them in the hinterland. This will produce safer and quicker results.

Early in 1956, in his "On the Ten Relations," Comrade Mao Zedong specifically expounded the matter that the coastal areas should support the hinterland. Liu Shaoqi and Zhou Enlai also repeatedly stressed that full play should be given to the role of coastal areas and support should be rendered to the construction of the hinterland. Since the 1950's, a vast number of cadres and workers have been transferred in succession from Shanghai and other coastal cities to strengthen the industrial construction of the hinterland. Some trades have organized technical service teams according to products and big economic districts to provide the hinterland with technical assistance and carry out activities to provide experience in the hinterland. Over the recent past 2 years, the industrial departments of Jiangsu, Hubei, Shizhuan and Heilongjiang provinces further carried out the activity of learning from Shanghai, centering on improving product quality, increasing the variety of product design, color and size and enhancing production techniques and management skills. This resulted in marked achievements.

The level of production has been improved. After following the activity of "Learning from Shanghai and reaching the targets," the textile trade of Jiangsu Province fulfilled in 1980 a total output value of 9.15 billion yuan, an increase of 28 percent over 1979; produced profits of 1.1 billion yuan, a 34 percent rise, and earned foreign exchange of $450 million a 10 percent gain. In the past 2 years, 13 products were awarded gold and silver medals, 46 items were graded as national brand-name products, 364 items as national products of fine quality, 57 items as provincial products of fine quality, and 413 new products and new varieties of product design, color and size were put into production.

The backwardness of a number of less advanced enterprises has been ended. Since the end of 1979, the Wuhan No 2 Ligh Industrial Bureau has organized 96 enterprises which center on learning from Shanghai. They have fulfilled 29 projects, solved 66 key problems in production, resulting in relatively great changes in 25 enterprises out of the 96. Take the spokes produced by the Xinyang County bicycle spare parts plant for an example. The inferior spokes of the plant were overstocked and rejection of substandard products was so serious that plant production had to be suspended in 1979 to rectify this matter. Through the help rendered by the comrades from Shanghai, the plant overcame key technical problems and its product quality surpassed the standards set by the ministry concerned. Now the products of the plant not only are on sale throughout the country but also are being exported in large numbers.

The business management of enterprises has been improved. The Harbin pencil factory learned in earnest from the Shanghai No 1 pencil factory, and other units, experience in business management, perfected the responsibility system, carried out the overall quality management and business accounting, strengthened the building of teams and groups, improved the methods for rewards, defined the policy of product diversity and developed products of fine quality and adopted the business principle of small profits and quick turnover. The rate of regular production has improved, its administrative expenses have dropped, the varieties of goods on sale on the domestic and foreign markets have increased. In the first 2 months of this year, the factory had an additional income of over 200,000 yuan.

The staff members and workers have received training. The localities and enterprises which were engaged in learning from Shanghai assigned relatively efficient staff members and workers to take the comrades from Shanghai as their teachers and learn techniques from them, and invited the comrades from Shanghai to start professional training courses and technical lectures, and trained a group of backbone staff in techniques and management, thus enabling the staff members and workers to learn the good ideas and work style from Shanghai's working class.

The practice shows that if the industrial departments of the hinterland learn from Shanghai and proceed from reality to transplant the experience of Shanghai they can effectively promote the development of local industry, help improve the national economy as a whole, can more effectively raise the scientific, technical and cultural level of the whole nation and also more effectively control the growth of population of big cities and assist in the construction of medium-sized and small cities and towns. This is of great significance in improving the economic effect and the acceleration of the four modernizations program.

According to the experience of some localities and in the light of past experience, in commencing to learn from the advanced, attention should be paid to the following things; 1) "Uphold the principle of giving prominence to ideological work and raise the conscientiousness of study." Learning from Shanghai is not a problem of method, but a way to give full scope to the superiority of the socialist system, to stick to the principle of self-reliance and carry out the four modernization program in the spirit of achieving greater, faster, better and more economic results. Therefore, it is imperative to conduct thoroughgoing and painstaking ideological work and rectify the following incorrect ideas: The experience of Shanghai is too high to attain, thus there is a lack of confidence in studying it; and its level of production is high and unattainable. Because their own products are selling well, some people feel that it is unnecessary to learn any more; some people are unrealistically satisfied with their own achievements in some respect; they are unwilling to learn because it requires too great an effort to learn from Shanghai. We must learn from the experience of Shanghai conscientiously, earnestly, assiduously and persistently. The comrades from Shanghai who were assigned to help and learn from the comrades of the hinterland should stress ideological education. They should bring into play the spirit of socialist cooperation, advocate the approach of "acting as host but not as guest," manage to pass on experience in an earnest and sincere manner and enthusiastically solve the problems on their own initiative.

2) "Adopt varied effective ways of study in the light of the actual conditions." The ways of study for the time being are chiefly: first, organize economic cooperation. It is necessary to give scope to Shanghai's strong points in techniques and equipment and the hinterland's strong points in raw materials, factory building and manpower, and form various forms of economic complexes including integrated enterprises, jointly-operated enterprises, branch factories and compensation trade. Second, establish a fixed relation of helping and learning from each other among the enterprises. It is necessary to link up some selected backbone enterprises with Shanghai enterprises of the same types and the latter should not only pass on techniques and experience but also render assistance in technology, equipment, spare parts, informaton and data. Third, Shanghai can send complete three-in-one teams integrating leading cadres, technical personnel and veteran workers to help the enterprises of the hinterland solve the key problems in production in detail. Fourth, a technology. It is necessary for the both parties to sign a contract stipulating the coordination, requirements, time limits and methods for payment. Payment according to work done can be generally adopted and technical service charges and expenses of man-day and materials can be paid in a single or in several payments. They can share a certain proportion of the net profits or the profits in excess of the production targets of the completed joint projects. As for the activities of helping and learning from each other that consume little amount of work and time on a mutual voluntary basis, free instruction can be practiced or the group receiving instruction can bear the wages, bonuses, subsidies, medical expenses and official business and traveling expenses of the helping-and-learning personnel from Shanghai. Fifth, invite the retired workers and technical personnel from Shanghai to pass on experience. Most of Shanghai's retired workers and technical personnel are superb in techniques, rich in experience, high in consciousness and good in their work style. They are valuable assets of the state. To invite them to strengthen the work of the hinterland can have a great effect. Sixth, send people to Shanghai to "learn from its experience," receive training, go on field trips and visiting trips and attend the training courses, on-the-spot meetings and meetings for exchanging experience sponsored by Shanghai. The abovementioned methods of "inviting in and sending out" must be carried out step by step with a definite emphasis. It is advisable to go to Shanghai in small numbers, and not permissible for people to quickly pour into Shanghai. Besides, the experience of Shanghai can be compiled into data and be made into films. Various localities can start study classes and research classes on learning from Shanghai.

3) //In the light of the imbalances of the development of localities and enterprises, put the classified guidance into effect and integrate the local advanced experience.// For instance, Suzhou, Wuxi, Changzhou and Nantong which are relatively developed

in the textile industry in Jiangsu stressed learning from Shanghai, while Nanjing and Xuzhou put the stress on learning from these four cities. The products of the Nanjing textile trade were in the past never on the lists of public appraisal of product quality. After it took Changzhou and Wuxi as its examples to learn from and to catch up with, in 1980 three items of its products have been graded as brand-name products, 10 items as national products of fine quality and 53 items as provincial products of fine quality. According to the level of technical and economic targets, the level of quality and variety and the enterprise business management skills, Jiangsu Province arranged the enterprises in order of importance and urgency. They were classified into three categories: first, second and third. The enterprises of the first category should learn from Shanghai and are required to reach the level of production of Shanghai in a certain period of time; those of the second category should learn from those of the first category, that is to say, they should first catch up with and surpass the advanced level of the province; and those of the third category should center on rectification and putting an end to the backwardness of the enterprises in a limited time. Thus the activities to learn from Shanghai were carried out grade by grade and step by step, and the way of "finding a single solution for diverse problems" was no longer adopted. This helped improve greatly the level of the whole trade.

4) //Take hold of typical examples to promote the work as a whole and organize the activities of learning from Shanghai in a coordinated sequence.// In studying anything, one must have a clear target, focus on solving one or two key problems, and must not place undue emphasis on quantity or completeness. Instead one must strive for quicker results. In learning from Shanghai, the Shizhuan textile trade first invited Shanghai to send experienced personnel to conduct investigation and study to find out the real conditions, and decided to take four factories of Chongqing as the key and concentrate on resolving the problems that demand a prompt solution in developing present production, such as the quality of the fabrics of medium and long fibers, the quality of printing and dyeing polyester and cotton cloth, the techniques to straighten the finished polyester and cotton cloth and the techniques to print sheets. After that, Shanghai organized helping-and-promoting groups with complete composition of personnel to carry out the work in these four factories, with the participation of the selected personnel of the Chongqing textile trade. Using these four factories as the "models," the Chongqing textile trade organized the enterprises concerned to carry out the activities in a coordinated sequence to tackle key problems from spinning, the making of grey cloth and printing to finished products. The promotion of the work as a whole by using typical examples and the integration of the four factories with other factories enabled them to spread the experience of Shanghai to the whole trade at a faster speed through these four factories.

5) //Combine the learning and transplanting of advanced experience with the rectification of enterprises.// First of all, it is imperative to further strengthen the building of groups which lead enterprise. Sticking to old ways, without the willingness to study and without a definite cultural and professional level, it is hard for the leading groups to learn things. Secondly, it is necessary to amplify the responsibility system, comprehensive quality management business accounting, and fixed quota management and set up the corresponding economic management system in order to help the results of study really take effect in the enterprises in terms of organization, system and measure. It is also necessary to vigorously train every

staff member and worker, enhance the scientific research, designing and trial-manufacturing capabilities of products and effectively improve the level of production techniques of the enterprises.

6) //Enhance the organizational leadership, stress the practical results and avoid blindness.// In the past in launching the campaigns for learning from the advanced, undue emphasis was very often placed on formalism, ostentation and extravagance. People used to rush headlong into mass action in an unplanned way and sought a superficial grand spectacle, disregarding the practical economic effect and wasting a large quantity of manpower, material resources and finances. It is essential to draw lessons from these acts and carry out the activities of learning from Shanghai, coastal areas and the advanced in a down-to-earth manner. In accordance with the policy of readjustment, the various departments and localities should determine where they lag behind such as in economic and technical targets, enterprise business management, production techniques, industrial organizations and economic reform, and analyze the reasons, designate the targets and work out the plans for catching up and learning. After being balanced by the departments concerned in an overall way, the plans should be carried out in a planned and organized way and step by step. In studying, one must have a definite aim in view and learn in order to practice. The personnel should be complete and small in number but highly capable of resolving practicel problems. We must not carry on any political movements, do anything perfunctorily, indulge in extravagance and waste or drag in logs of people, all of which would adversely affect production. The learning side and the helping side should sign a contract and after the completion of the learning and helping activities, the results should be checked before acceptance and implementation in earnest. As for Shanghai, its industrial departments concerned should make overall arrangements for heoping other localities. They can set up technical advisory bodies and service centers to arrange in a unified way the transfer of techniques, management and qualified personnel to "diagnose a disease" for the enterprises of the hinterland, provide them with data, transfer knowledge of techniques to them, install equipment and oversee its initial operation, resolve key technical problems, improve the business management, train the technical operating personnel and start professional training courses.

'JINGJI GUANLI' REPORTS ON ECONOMIC REFORM FORUM

HK270238 Beijing JINGJI GUANLI [ECONOMIC MANAGEMENT] in Chinese No 7, 15 Jul 81
pp 17-22

[Article in the special collection of articles (Part II) on the reform of economic management systems: "Summary of the Forum on the Theoretical and Practice Aspects of the Reform of Economy Management System (Written on 25 April 1981")]

[Text] At the suggestion of the leading comrades of the State Council, the Industrial Economic Research Institute of the Chinese Academy of Social Sciences and the Sichuan Social Sciences Research Institute jointly sponsored the convention of the "Forum on the Theoretical and Practical Aspects of the Reform of Economic Management Systems" in Chengdu from 16 to 25 April, 1981. The forum was attended by 351 persons, including workers in economic theory, practical workers in economic departments, and comrades from experimental enterprises. Some 120 theses and pieces of compiled information were presented during the forum.

This forum did not aim at pure theoretical discussion. Instead, it demanded the linking of theory to practice, the summing up of experience in readjustment and reform, and the presentation of some constructive ideas for consideration by the leading bodies concerned.

At the opening ceremony of the forum, Comrade Ma Hong [7456 3163] communicated the gist of the recent speeches of the leading comrades of the State Council as well as their demands on the forum, and Comrade He Haoju [0149 6787 3515], secretary of the Sichuan Provincial Party Committee, delivered a speech. During the forum, Comrade Lin Ling [2651 0407] made a special report entitled "The Situation of the Reform of Economic Systems in Sichuan Over the Past 2 Years, and Expectations of Future Developments" and Comrade Jiang Yiwei [5592 0001 5517] delivered a speech to the whole forum entitled "The Essence of the Reform of Economic Managements Systems Is To Achieve Socialist Economy Democracy." At the closing ceremony, Comrade Ma Hong delivered a concluding speech entitled "By Means of Readjustment and Reform, Open up a New Path of Developing our Country's Socialist Economy."

This forum was convened at a time when the principle of readjustment is being implemented to a further extent. All comrades at the forum believed that if we want to open up a new path for our country's economy which is compatible with our national condition and which can fully improve the economic results, we must rely on first, readjustment, and second, reform. Through readjustment, we must reduce the scale of the capital construction front, economize in the use of administrative funds, achieve equilibrium in fiscal revenue and expenditure, and gradually rationalize our economic structure, organization and systems on the basis of economic stability. Therefore, it is quite necessary to conscientiously sum up practical experience and discuss important theoretical and practical problems. Throughout the forum, the principle of letting a hundred flowers blossom and a hundred schools of thought contend was adhered to. People freed themselves from old ideas and spoke freely. Integrating theory with practice, they enthusiastically discussed various issues, such as the aim of readjustment, the steps to be taken in readjustment, and corresponding measures of reform; rectification and improvement in the course of expanding the enterprises' decisionmaking power; the leadership system in the enterprises; the reorganization and intergation of enterprises; regulation by market mechanism under the guidance of planning and so on. A number of constructive ideas were put forth.

I. On the Aim of Readjustment and Steps To Be Taken in Readjustment

All comrades at the forum held that at present, readjustment must be taken as the central task and reform must be subordinated to readjustment, and that nevertheless, this definitely does not imply that reform may come to a halt. On the contrary, many readjustment items cannot be divorced from reform, and moreover, many reform items are advantageous to readjustment. Readjustment and reform complement each other and must be carried out simultaneously.

The comrades at the forum disagreed with the view that certain current economic difficulties have been caused by reform. It is natural that there are defects in our reform at this stage of experimentation. The main question is whether macroeconomic control has been keeping pace with developments. We should strengthen macroeconomic control and guidance on the basis of enlivening microeconomic activity, instead of smothering microeconomic activity by old methods of centralized control. Following the beaten track is not the way out.

All comrades at the forum agreed that the ultimate goal of readjustment and reform should be the rationalization of our economic structure, organization and systems, and that we should work out complete plans which we should implement in stages step by step.

The achievement of the rationalization of these three things is expected to take 10 years or even more. We envisage three possible stages to achieve rationalization.

The first will be the stage of economic stabilization. The principal tasks of this stage will be to strictly control capital construction investment, to vigorously develop the production of consumer goods, to achieve budgetary equilibrium, price stability and economic stability, and thus to enable the people to enjoy continuous improvements in livelihood under the condition that the current income level can be maintained. This stage will last about 2 years. The second will be the stage of coordinating the proportions of agriculture, light industry and heavy industry. In this stage, the key task will be to further readjust the proportions of agriculture, light industry and heavy industry, so that the relationship between the two major categories of social production will be basically well coordinated, and so that continuous improvements in the livelihood of the people in urban and rural areas, as well as increases in the income of those workers receiving low wages, will be ensured. This stage will last approximately 3 years. The third will be the stage of the preliminary rationalization of our economic structure. At this stage, the key tasks will be to solve the problem of backwardness in basic facilities such as energy resources, transport, postal services, telecommunications, and so on; to establish relatively well coordinated relations between industry and agriculture, among various sectors of industry, among various sectors of agriculture and between industry and the infrastructure; and thus to make possible, marked improvements in economic benefits, relatively rapid growth in the people's income, and relatively great improvement in the people's livelihood. We will strive to achieve, at this stage, a rate of growth in the urban and rural residents; average level of consumption that will approach the rate attained during the first 5-year plan period. This stage will last approximately 5 years.

The majority of the comrades believe it is possible that with the accomplishment of the tasks of the second stage, the grave disproportion in the major national economic relations will be overcome, the potential dangers will be eliminated, and the readjustment period that we now talk of will come to an end. However, by that time, the tasks of rationalizing our economic structure will not have been completely accomplished. Even after the accomplishment of the tasks of the third stage, we will have to continuously readjust our economic structure in the light of the domestic and foreign economic situations of that time, and in the light of changes in social needs and technological conditions of production.

II. On Expanding the Enterprises' Decisionmaking Power and on the Correct Handling of the Distribution of Benefits Among the State, the Enterprise and the Worker

The comrades at the forum enthusiastically discussed the issue of expanding the enterprises' decisionmaking power. They all held that, with regard to the reform of systems over the past 2 years, which has been based on expanding the enterprises' decisionmaking power, it orientation has been correct, its development has been healthy, and its results have been marked. The experiences of Sichuan, Shanghai and other localities have played a beneficial role in promoting the reform. The current problem is how to carry out further rectification and improvement on the basis of our experience.

The comrades at the forum held that in order to perfect the experimental methods, it is of key importance to correctly handle the economic relationships between the state, the enterprise and the individual worker. Various forms of distribution of profits have their own advantages and shortcomings. Different methods should be adopted by different enterprises. It will be wrong for "all people in the country to wear shoes of the same size." The majority of the comrades held that if the ratio is appropriately set, it will be rather rational to divide the whole profit between the state and the enterprise, so that both the state and the enterprise will obtain a larger revenue or income when the profit is larger, and vice versa, just as "a boat goes up at high tide and goes down at low tide."

During the discussion, there were different views on how to determine a reasonable proportion of retained profits. There was a general view that we need to further study both the macroeconomic and microeconomic aspects, and we must both ensure the state's fiscal revenue and consider the enthusiasm of the enterprise. In view of the practical experience in expanding the enterprises' decisionmaking power, under present conditions, the average proportion of profits retained by the enterprises should not be lower than 10 percent, but also must not be too high. Moreover, different proportions should be applicable to different trades or enterprises.

In distributing profits between the state and enterprises, should we take a trade, or should we take a company, as the basis for unified distribution? It was generally held that, judging from practical experience, each of these two methods has its own advantages and shortcomings, and we cannot say in general which one is better.

The nature of retained funds is an important theoretical and also practical issue brought up during the discussion. Many comrades held that we must not regard the enterprises' retained funds as belonging solely to the enterprises. The funds should be categorized, according to their nature, into funds "owned by the whole people and at the disposal of the enterprise," and funds "owned by the enterprise and at the disposal of the enterprise." These two categories of funds should be handled according to different principles.

Considering the nature of bonuses and the criteria governing their distribution, it was generally held that when the state distributes bonuses to the enterprise, or when the enterprise is distributing bonuses to the individual, the distributor must implement the principle of distribution according to work done. It is desirable to rename reward funds as extra-dividends funds,because the latter reflects the fruits of the enterprise's subjective efforts in collective production and operations. Employing various methods, such as calculating bonuses on the basis of recorded workpoints, fixing bonuses for fulfilling tasks undertaken, distributing bonuses on a collective basis, or other methods which are closely integrated with comprehensive economic accounting, the enterprise should distribute bonuses to smaller collectives and individuals according to the magnitude of contribution in the overall effort.

It is a general view that appropriate state control over bonuses is necessary, but the present methods of control are not rational. The majority of the comrades thought that bonuses should be linked to profits. We may set a ceiling, and then fix the increase in bonuses in relation to the growth in profits. For example, a bonus may increase by a fixed absolute amount with a given percentage increase in profits. Alternatively, we may prescribe various levels of bonuses in relation to the necessary and expected profit figures in the plans, and so on.

All comrades at the forum held that in order to consolidate the positive results of expanding the enterprises' decisionmaking power, during the period of readjustment, we should sum up our experience, do a good job of carrying out the synchronized and complementary reform, and lead the superstructure to becoming compatible with the needs of the development of the economic base, instead of, on the contrary, adopting the method of "recalling power" or reverting back to the beaten track. To do a good job of carrying out the synchronized and complementary reform. We should solve three problems at present: first, we must define rational limits for the experimental enterprises' power over human, financial and material resources and over production, supply and marketing; second, we must gradually resolve the contradictions between the present systems and the expansion of power; third, we must solve the problem of the subordination of numerous higher authorities.

We must strengthen macroeconomic control and guidance on the basis of enlivening microeconomic activity. However, the policies, stipulations and methods that we hope to formulate must be based on hearing the opinions from an extensive range of different quarters and having a thorough grasp of the situation, and must be thoroughly studied, discussed and considered before they are made known to the lower levels. Once they have been decided upon, they must not be modified frequently, and must be implemented by all departments concerned, which must not do things in their own ways.

III. On Paying Taxes Instead of Turning Over Profits to the State, and on Assuming Sole Responsibility for Profits and Losses

Theorists have two different views on whether the enterprises under the ownership of the whole people should assume sole responsibility for their own profits and losses. The majority of the comrades at the forum held that it is necessary and also possible for our country's socialist state enterprises to assume sole responsibility for their profits and losses or to practice the responsibility systems for profits and losses. To do so will be in line with the orientation of development in expanding the enterprises' decisionmaking power, putting an end to the system of centralized collection of revenue and centralized spending, solving the problem of inequity among the enterprises with regard to material benefits, and reforming our economic systems. The reasons are: first, at the present stage, the socialist economy of our country is a commodity economy subject to planning, and the enterprises are relatively independent producers of commodities. Therefore, the enterprises should follow the principle of operations and management that applies to all commodity economies, that is, the principle of assuming sole responsibility for their profits and losses. Second, with the assuming of sole responsibility for profits and loses, the achievements of the enterprises in production and operations will be more closely integrated with their staff and workers' economic interests; the enterprises' powers, responsibility. Economic results and interests will be more satisfactorily integrated; and the enterprises will have internal motivation and will be subjected to external pressure, so that the enthusiasm in production by the enterprises and their staff and workers will be more satisfactorily mobilized. Third, the practice of experimentation in various localities has also testified that the overall results of assuming sole responsibility for profits and losses are good. Of course, the specific methods of implementation need to be perfected.

Some groups discussed the adoption of different methods of operations and management by different types of enterprises. It was generally agreed that the numerous small enterprises which mainly depend on manual labor should change over to assuming sole responsibility for profits and losses as soon as possible. However, there were different views on certain ideas and theoretical bases. It was argued that it is not scientific to categorize the enterprises on the basis of two factors only, namely, the human factor and the material factor. It was also generally held that for those enterprises with a flexible funding structure or with a high technological standard, it was equally necessary for their operations and management to be well performed and for the enthusiasm of them and their staff and workers to be fully mobilized; otherwise, the economic results would still be poor. Some comrades believed the first type of enterprises (namely, those with a flexible funding structure) can just practice "collective assumption of responsibility for profits and losses." The consensus was that this will inevitably lead us back to the beaten track we followed before the reform of our systems, and will lead to the recurrence of old problems. Practice has proved that by adopting the method of "collective assumption of responsibility for profits and losses," we will not attain the goal of mobilizing the enthusiasm of the enterprises and of their staff and workers.

Considering the issue of substituting taxes for profits, all comrades held that it is an objective requirement of, and also an inevitable trend in, the development of our reform of economic systems, to require the state enterprises to pay taxes according to unified methods instead of turning over profits to the state, and to assume sole responsibility for profits and losses, when the reform of economic management systems continues to develop in depth. Substituting taxes for profits is not merely a change in the method of turning over profits to the state, but amounts to an important reform in the relationship between the state and the enterprise in the distribution of benefits, and is an important measure by which the state manages the economy by economic means. By substituting taxes for profits, not only will we be able to change the enterprise into a really dynamic economic entity, but also will be able to relatively thoroughly free the enterprise from the fetters of the financial system of "centralized collection of revenue and centralized spending." Moreover, this measure will also be conducive to removing the boundaries between various departments or localities, and it will thus help promote economic integration and reorganization.

Under the condition of socialism, taxation is not merely a means by which the state accumulates funds, but it also plays the role of regulating social production. At present since major changes in commodity prices are impossible, to appropriately put an end to the inequity among the enterprises in matters of material benefits, and to launch emulation drives and competition with all parties concerned being placed on the same starting line as far as possible, we must pay special attention to bringing the role of taxation as an economic lever into play. This constitutes an important task in the reform of economic management systems. In the past, because we did not acknowledge the socialist economy as a commodity economy subject to planning, nor did we acknowledge the actually existing differences in interests among the enterprises as relatively independent producers of commodities, we neglected the regulatory role of taxation. Thus, in various past reforms of the taxation system, we simply emphasized simplication, so that the types of taxes continued to decrease in number, and the role of taxation continued to diminish.

The comrades at the forum discussed the questions of types of taxes and tax rates, and had put forth some specific views. There were various views on the present stipulations governing the income-regulation tax. It was thought that the main problem with such stipulations is that they do not embody the distinguishing of subjective factors from objective ones, and they cause all the enterprises' additional income to be transferred to the state, so that the enthusiasm of the enterprises in improving management and operations is dampened.

IV. On Reforming the Leadership System Practiced Within the Enterprises

The representatives at the forum enthusiastically and seriously discussed the "recommendations on the experimental reform of the system of leadership in state enterprises" (draft--opions on which are invited). It was generally held that the "recommendations" are practicable and relatively compatible with the real situation.

It was hoped that they can be communicated to the lower levels as soon as possible, and can be further amended and perfected with practice. Some specific proposals on amending the "recommendations" were put forth.

Among the questions concerning the experiments in reform, the question of leadership of the party committee over the enterprise has been the most controversial one, and the one on which differences in views have been greatest. The representatives at the forum discussed this question in relatively great depth, and analyzed the cause of the problem in the ideology and understanding of many comrades, who have been unable to get their thinking about reforming the system of leadership over the enterprises straightened out. The consensus was that the aim of reforming the system of leadership over the enterprises and effecting division of labor among the state, the government and the enterprise is definitely not to weaken party leadership, but is precisely to strengthen and improve party leadership over the enterprises. However, to ensure the improvement and strengthening of the leadership of the party committee over the enterprise, we must clearly understand the several questions discussed below.

First, we must clearly understand the status and role of the party committee of the enterprise. The party committee is a grassroots organization of the CCP in the enterprise, and is the core of ideological and political leadership over the enterprise. By means of persuasion, education, enlightenment and various other democratic methods, the party committee of the enterprise must exercise ideological and political leadership as well as supervision over the administrative bodies of the enterprise, the staff and workers' congresses, the trade union, the Communist Youth League and the whole staff. It must thus ensure the implementation of the party's line, principles and policies in the enterprise and also the fulfillment of various economic tasks.

All comrades thought that it is very important to clearly understand this point. With the accomplishment of the reform, the party committee will be unable to exercise direct command over production and administrative work or to issue orders accordingly, and will not have the power to decide on or veto the work of the staff and workers' congresses. Nevertheless, as an entity, the enterprise will certainly need to have a core to unify everything. This core can only be the party committee of the enterprise. Moreover, only the party committee will be able to play this role. Without it, it will be impossible to have unified thinking and actions in the enterprise.

Some time ago, precisely because, in envisaging the reform, we did not explain this point clearly or prominently, and because we merely emphasized the party committee's role in ensuring the realization of things desired and its role in supervision, many comrades have not got their thinking straightened out.

Second, we must clearly understand the tasks of the party committee within the enterprise. The principal task of the party committee is to ensure the implementation of the party's line, principles and policies in the enterprise. Therefore, it must conscientiously do a good job of building the party ideologically and organizationally, and fully bring its role as the core of political leadership into play. Taking production as the central goal, it must do a good job in ideological and political work, raise the staff and workers' political consciousness, and enhance their sense of responsibility in regard to their roles as the masters. It must help fully bring the role of the staff and workers' congresses into play, and must give support to, and exercise leadership over, the mass of staff and workers, in their endeavor of correctly exercising their rights as the masters, managing the enterprise well and correctly handling the relations of economic interests among the three parties: the state, the enterprise and the individual. It must support the factory director so that he will be able to effectively exercise command over production techniques, management and operations. It must teach the party members and cadres to take the lead in implementing, the factory director's directives. It must teach the masses to consciously abide by factory rules and regulations, and to subordinate themselves to the factory director's command. The party committee must thus play its role as the core of ideological and political leadership. It must also coordinate the relationships between the administrative bodies of the enterprise, the staff and workers' congresses, the trade union, the communist youth leagues and so on. It must ensure that the whole factory works satisfactorily and in unison.

Third, the party committee must alter its methods of work. It must change over from direct administrative leadership to ideological and political leadership.

V. On Industrial Reorganization and the Integration of Enterprises

All comrades at the forum held that it is an important task in the current readjustment and reform to do a good job of reorganizing industry and integrating enterprises according to objective economic laws and the principle of coordination among specialized units.

The forum emphatically discussed the following few questions.

What path of industrial reorganization and integration should be taken? The comrades at the forum summed up the lessons of the experience over the past 2 years, and held that we should integrate from-bottom-to-top consultations with the requisite administrative leadership, according to the principle of democratic centralism, and adhere to the practice of voluntary action and mutual benefit. Especially at present, when the departments and localities are so severely separated that industrial reorganization and integration are seriously hampered, it is even more essential to rely on administrative power to break the boundaries among departments and localities, and thus to pave the way for reorganization and integration.

In integrating enterprises, we should adopt many forms, proceed from the reality, and proceed from looser integration to closer integration. We must not rely on a single method, or categorize things sweepingly according to some simplistic criteria. Existing administrative companies should gradually change to become companies which are enterprising in nature. We must continue to fully exploit the role of those specialized companies which can help promote reorganization and integration. We should resolutely straighten out those companies which are "as lacking in vitability as an old grandmother."

All comrades at the forum believed that "substituting taxes for profits" is an effective measure to break the boundaries among departments or localities and to promote reorganization and integration. They proposed expanding the scope of experimentation and applying this measure to companies which extend over a number of departments or localities. Moreover, we must solve the problem of double taxation imposed on factories which practice cooperation, and we must introduce the added value tax on a trial basis as soon as possible.

At the forum, the comrades enthusiastically discussed the question of the setting up of trade organizations by production units of the same trade. The general view was that such trade organizations may be called trade associations. Each of them will be a democratic consultative agency, to be voluntarily organized by production units of the same trade, and to coordinate the development of the trade. Such a trade association will differ from a government administrative body, and it will have powers of coordinating its members and imposing constraints on them. It will not be an economic entity, but it will have definite economic functions. To manage the enterprises by means of the trade association is a reflection of socialist economic democracy. The trade association will be able to serve as a bridge between the enterprises and the government or a means of linking various enterprises. It will help us to break up the boundaries between departments or localities, to more satisfactorily promote reorganization and integration, to improve the degree of socialization of economic activity, and to enable the enterprises to organize themselves into networks according to objective laws. At the forum, the functions, organizational forms and methods of organization of the trade association were also studied specifically.

The forum also discussed the question of setting up economic centers. It was generally held that historically, the development of certain cities (or towns) into economic centers of certain regions was a reflection of objective laws of economic development. Bringing the role of economic centers into play will be an important condition for promoting reorganization, integration and economic development.

The comrades at the forum held that the concept of large and medium-sized cities is not identical to the concept of economic centers. Economic centers must necessarily be formed in certain large or medium-sized cities. To establish and develop economic centers, we must presently assign the requisite powers to large cities. However, an economic center differs from a large or medium-sized city in that it is an economic organization instead of an administrative one. It should be a body in a large city, composed of various trade organizations. Under government leadership, it will coordinate the relationships between one trade and another, and it will handle problems common to all trades. At present, we should empower the governments of large cities to formulate overall plans for reorganization and integration, to promote the integration of enterprises, and to support the establishment of trade organiaations. When reorganization and integration have reached a certain scale, organizations of the nature of economic centers should be formed democratically.

The comrades at the forum held that, considering industrial organization, the signs of the rationalization of economic organizations include the following. 1. The government and the enterprise will be gradually separated, so that the enterprise will no longer be directly linked to the government departments concerned and the local government. Thus it will become a relatively independent producer of commodities. 2. The enterprises will be organized into various economic conglomerates according to the principles of economic rationality and coordination among specialized units. 3. Trade organizations will be established, and entire trades will be subjected to democratic management will transcend trades or localities. 5. The government will strengthen its management and control of macroeconomic activity on the basis of economic democracy.

VI. On the Planned Economy and Regulation by Marked Mechanism

The leading comrades of the CCP Central Committee have recently pointed out that we must study how to define some limits on the planned economy and regulation by market mechanism. The comrades at the forum held that it is a very important problem. It is a specific embodiment of the problem of fully bringing the role of the market into play under the guidance of planning.

What amounts to regulation by planning mechanism? What amounts to regulation by market mechanism? What relations exist beteen these two types of regulation? Views on these questions differ greatly among the theorists. The views expressed at this forum also differed. Therefore, there have been different views on how to define limits.

All comrades at the forum thought that with the implementation of regulation by market mechanism on a partial basis over the past 2 years, the integration of production with needs has been strengthened, competition has been launched, the improvement in running and managing the enterprises has been promoted, and the channels of circulation have been extended. Thus, implementing regulation by market mechanism has been very effective in enlivening the national economy and helping to readjust the production structure. Great success has been achieved and must be fully affirmed. However, many problems have also occurred because macroeconomic control, the management of the market, and so on, which have not kept pace with developments.

Many comrades thought that a socialist economy is a planned economy, and the role of the market can just be a supplement to the planned economy. The concept of "regulation by planning mechanism" is not precise enough. The problem is to strengthen "macroeconomic control." To achieve this, we must take a variety of measures, including guidance by means of plans, guidance by providing economic information, the use of economic levers, supervision through economic legislation, carrying out administrative management as necessary, and so on.

There were also some comrades who thought that planning, by its nature, can play merely a guiding role. Theoretically speaking, it is wrong to divide plans into "guiding" plans and "directive" ones. At present, the so-called "directive plans" actually refer to direct state control over the production of certain products and over certain construction projects. Therefore, some comrades thought that instead of having "directive" production plans, it is better for us to have the state ordering goods. Moreover, because the plans formulated by the state include the ordering of goods by the state and also forecasts goods which are not ordered by the state, therefore, the plans as a whole essentially provide guidance, but the stipulations concerning the ordering of goods come in the form of directives. However, the ordering of goods by the state amounts to an economic act, in which both the state and the enterprise have their own rights and obligations. This economic act differs from "directive planning," which involves merely the assigning of targets to lower levels, and which implies that the state enjoys rights without having to shoulder economic responsibility.

The so-called regulation by planning mechanism essentially refers to direct state control over the production and circulation of products. It is a general view that the extent of control (that is, the question of defining limits) should be determined in the light of the following factors.

1. The extent of the market for the product: there must be greater control over products to be sold on a nationwide scale, whereas there may be less control or no control over products that are produced and sold locally.

2. The status and role of the product in the national economy: major products that are important to the national economy and to the people's livelihood must be subjected to stricter control or must be solely purchased, marketed and allocated by the state in a centralized manner.

3. The situation of the demand for and supply of the product: there must be greater control on important products which are in short supply.

4. The situation of ownership of the means of production;

5. The scale of the enterprise: there must be greater control over large enterprises and less control over medium-sized and small ones.

To effect the control that we have mentioned, we may adopt the form of the ordering of goods. For some products, the state may place orders and purchase them monopolistically according to plan, without purchasing the output in excess of planned targets. For some other products, the output in excess of planned targets must also go to the state, but the prices of this extra output may be appropriately raised as a form of encouragement. For a third category of products, the state will not place orders for them, and the enterprises will have to seek on their own ways to sell them. The production of such products will be regulated by market mechanism. On the other hand, a portion of those goods ordered by the state may also be offered for sale on the market, by the state, in a planned way.

NATIONAL POLICY AND ISSUES

TRUST, INVESTMENT COOPERATIONS

OW171110 Beijing XINHUA Domestic Service in Chinese 0258 GMT 17 Aug 81

[Text] Beijing, 17 Aug (XINHUA)--Since implementing an economic open-door policy, our country has achieved initial results in opening avenues of economic cooperation and technical exchange with other countries and making full use of foreign capital. Following the establishment of the China International Trust and Investment Cooperation, 16 provinces and municipalities have successively set up trust and investment cooperations or have restored overseas Chinese investment cooperations.

It has been learned that since their establishment or restoration, these cooperations have been engaged in business in the following aspects:

Organizing joint ventures using Chinese and foreign investment and cooperative enterprises: According to incomplete statistics, eight earlier-established trust and investment cooperations, which have been commissioned by foreign companies to maintain contact with enterprises at home for them, have helped to set up nine joint ventures using Chinese and foreign investment and 45 enterprises run through cooperation between Chinese and foreigners in the past 2 years. In accordance with the terms of their contract, these joint ventures and cooperative enterprises have a total investment of $158.23 million. The China International Trust and Investment Cooperation has invested more than $7 million in the molybdenum ore concentrate, phosphate ore and graphite electrode projects, achieving relatively good results. For example, plans called for the suspension of the construction of the Xiaosigou molybdenum mine. However, with investment by the cooperation, this mine has resumed production and has exported more than 500 dun of molybdenum ore concentrate in the past year, thus turning losses into profits. The passenger and freight ships jointly operated by the Fujian Investment Enterprise Cooperation and Hong Kong businessmen between Xiamen and Hong Kong shipped over 140,000 dun of exports, more than 130,000 dun of commodities for domestic markets and over 45,000 passengers in 1980, earning more than $8 million. After paying loan interest, they netted a profit of 1.88 million yuan.

Extensively organizing compensation trade and the processing of raw materials and assembling of parts provided, the Zhejiang Overseas Chinese Investment Cooperation has arranged compensation trade for the Hangzhou No 2 cotton mill with Hong Kong businessmen who have invested 3 million yuan in the mill. As a result, this mill has increased not only its foreign exchange earnings but also the number of workers by 1,100. The Guangdong Provincial Overseas Chinese Enterprise Cooperation has organized 10 projects for processing raw materials and assembling parts provided and for compensation trade, which have absorbed more than $16 million of foreign capital and have provided jobs for 2,700 workers.

Raising funds abroad in various ways to be invested in domestic construction projects: According to the statistics compiled by eight cooperations, they have obtained long- and intermediate-term loans from foreign banks and have absorbed deposits from overseas Chinese and compatriots in Hong Kong and Macao in the past 2 years, totaling about $108.25 million. In obtaining foreign funds on the principles of "obtaining foreign funds according to their payment ability and making appropriate use of them," these cooperations have been paying back such funds and making full use of them. The Tianjin International Trust and Investment Cooperation has raised $2.5 million and 8.5 million yuam for the Tianjin medium plate plant. This has made it possible for the plant to replace its rolling mills and auxiliary equipment and to rebuild its factory buildings. As a result, its annual output of steel plates has gone up by 70,000 dun, its specifications of copper plates have increased from a little over 30 to 120 and the quality of its products has reached export standards.

In addition, these cooperations, entrusted by domestic and foreign customers, provide them with business information and counseling.

ECONOMIC PLANNING

BRIEFS

ECONOMIC LAW RESEARCH CENTER--Beijing, 7 Aug (XINHUA)--According to the Zhongguo Fazhi Bao [China Legal System News], the Economic Laws and Regulations Research Center was recently established in Beijing. The center is a research and advisory organization under the leadership of the State Council. The main tasks of the center are: (1) to study the plan and steps for instituting and revising economic laws and regulations, research important theoretical and practical questions and make proposals to the State Council; (2) to organize, guide and coordinate with departments concerned to draft economic laws and regulations; (3) to study important economic laws and regulations handed down by the State Council and make suggestions for revision; (4) to hold periodic discussion meetings. [Summary] [OW200205 Beijing XINHUA Domestic Service in Chinese 1436 GMT 7 Aug 81]

LIAONING ECONOMIC RESEARCH CENTER--The Liaoning Provincial CCP Committee and the Provincial People's Government decided to establish a provincial economic research center to strengthen the socialist economic research and promote the readjustment of the national economy. This center is an advisory body subordinate to the Provincial CCP Committee. Zhu Chuan, Standing Committee member of the Provincial CCP Committee, is appointed as its director and (Yu Ran), (Zhang Lu) and (Xiao Meng) as deputy directors. [SK241245 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 22 Aug 81]

JILIN RESPONSIBILITY SYSTEMS--The Jilin provincial conference to exchange experiences in economic responsibility systems instituted at industrial and communications enterprises was held in Siping Municipality from 13 to 17 August. The conference noted that although profit-sharing and other economic responsibility systems has been extensively promoted at industrial and communications enterprises throughout the province, further improvement is needed. The conference urged efforts to fully understand the importance and necessity of the systems, continue to improve enterprise management and implement financial and economic discipline. Yu Ke, secretary of the Provincial CCP Committee and provincial governor, and Dong Xin, deputy provincial governor, attended the conference. (Li Dongpu), deputy director of the Provincial Economic Commission, spoke on current industrial production. [Changchun Jilin Provincial Service in Mandarin 2200 GMT 17 Aug 81]

'JIANGJI GUANLI' ON BANKING REFORM

HK220141 Beijing JINGJI GUANLI [ECONOMIC MANAGEMENT] in Chinese No 5, 15 May 81 pp 45-48

[Article by Li Shourong [2621 1343 2837]: "Reform the Banking System Actively and Steadily"--note passages within slantlines denote boldface type]

[Text] In the eight-character principle of readjusting, reforming, rectifying and improving being implemented at present, readjustment is the key link. However, readjustment and reform are mutually beneficial, as successful reform facilitates the work of readjustment. Reform of the banking system is an important part of the reform of the economic management system as a whole. An active and steady reform of the present bank management system by earnestly summing up past experience and lessons as well as by strengthening our investigation and research work for the purpose of giving it full play in regulating the economy undoubtedly is beneficial to economic readjustment as a whole.

(I)

Our present bank management system, by and large, was indiscriminately copied from that of the Soviet Union in the 1950's due to our lack of experience (the Soviet Union has long since reformed this system). Another part of our bank management system has been inherited from our banking experiences during the revolutionary war days. This system has made a certain contribution to our economic construction. However, during the 30 years after liberation, this system has not been touched by any reforms indispensable in the light of the specific conditions of our socialist construction and the principle of bank management by economic methods. As a result, many problems have accumulated. With the development of socialised large-scale production and a commodity economy, the shortcomings and drawbacks of this system have been all the more exposed. The following are the main manifestations: too much application of administrative methods, no application of management along the lines of an enterprise employing economic methods for banking, inadequate attention paid to economic efficiency, indistinct economic responsibilities for banks at various levels, the lack of economic motivation to do the work well in banks at the basic level, and inflexibility of the performance of the banks. To be more concrete, the following points may be summarized:

1. The operation of the banking business was limited to a narrow scope. For a long time in the past, banks were allowed to make only a part of the circulation fund loans to the industrial and commercial enterprises. Generally speaking, no

operation was allowed in the field of medium and short-term loans for equipment, loans for tapping potential, renovating and restructuring on the part of the old enterprises as well as loans to collective economic units and private individual households. Thus, the activity, the scope and the function of bank credit were very much limited, and it was impossible for the banks to play a fuller role even if they wished to.

2. The lack of flexibility in the extending of credit funds. All credit funds were collected and extended in a unified way by the head office. Banks at the basic level were not allowed to make more loans, even if they received more deposits. Credit funds of all sorts were controlled too rigidly and too little room was left for flexible adjustments. This was unfavorable to providing flexibility to bank operations.

3. The operation and management of the banks were gauged to a unified accounting system of the nation as a whole. This meant "eating out of a big pot." There was a lack of motivation to improve the standard of management and to pay attention to economic efficiency, which hampered the initiative of the masses of cadres to further expand banking operations.

4. The banks lacked independent authority to carry on banking operations. The banks very often were unable to make their own decisions in respect to making loans, many of which were decided by the local party and administrative authorities. The banks lacked adequate leeway to discriminate in order to select and support the better borrowers for their loans as well as to make their own terms of credit. Many loans were not redeemed in full at maturity. Consequently, the economic results of bank credit were rather poor.

Therefore, it is necessary to carry out the needed reforms in our bank management system in accordance with the general requirements of the economic management reforms of our country.

(II)

Since the 3d plenary session of the 11th CCP Central Committee, preliminary reforms have been made in our bank management system in the light of the principle of readjusting, reforming, rectifying and improving. The main reforms have been as follows:

1. A breakthrough has been made in the limitation of extending loans in the field of circulation funds only, thus expanding the scope of credit. In order to give vigorous support to the old enterprises in tapping potential, renovating and restructuring as well as to promote the development of the light and textile industries and to expand production capacity, the banks have made a certain number of medium and short-term loans in equipment financing, and in special projects financing light and textile industries. In many localities, banks have made appropriate loans in support of the cultural, research, tourism and service sectors as well as to certain urban collective units and private individual households which have the ability to repay and whose activities are in conformity with the state regulations. In some large and medium cities, banks have also tried trust and investment business. Besides, a certain amount of commercial credit was extended in a conditional and limited way. To a certain extent, this was helpful in enlivening the economy.

2. A preliminary change has been made regarding the unified collection and allocation of credit funds. In its place has been put into effect the credit management system of "unified planning, management by levels, linkage of deposits and loans, and the control of disparity. Within the allowed range of disparity, more loans can be made. This motivates the initiative of banks at all levels to raise more funds.

3. All loans that are overdue and those related to overstocking of supplies in excess of the stipulated reserves as well as those relating to financial expenses of all kinds are to be penalized by scaled-up interest payments in order to encourage the enterprises to economize on the use of funds and to make active use of the supplies and funds.

4. The domestic insurance work has been restored step by step. Domestic insurance business of every kind with property insurance of the enterprises as the mainstay has been initiated giving play to the superiority of the system of employing insurance to provide economic compensation.

5. Specialized banks (all directly subordinated to the State Council) are put into operation. Among them, the Chinese Agricultural Bank has been restored and the State General Administration of Exchange Control (the Bank of China) has been established. Consequently, rural financial work and foreign exchange management work as well as other work has been strengthened and developed.

As indicated by practice, these reforms are necessary and correct. They have yielded evident results in engineering the economy and motivating our readjustment work. However, all this is only preliminary. In order to give fuller play to banks, reform is to be continued gradually in regard to bank management.

First, the scope of the banking business is to be expanded in order to fully utilize credit to raise and allocate funds.// [First set slantlines missing]

From now on, with reforms of the economic system, on the question of systems of ownership, it is not only necessary to develop the system of ownership by the whole people that predominates in our economy, but also the collective economy as well as an appropriate amount of individual economy, allowing the coexistence of diversified economic elements. On the problem of the limitations of economic management power, the local authorities and enterprises should appropriately be given more autonomy. Enterprises, to a certain degree, will have their own say in respect to personnel, finance and assets as well as production, supply and sales. In regard to profits, the enterprises operate on a sharing basis. As a consequence, the inflow and allocation of profits of enterprises will not be totally controlled by the purse strings of public finance by way of unified revenue and expenditure. The local authorities and enterprises will have more and more funds and they want to make use of the funds. Then, who is responsible for organizing and distributing this part of the social funds. This task very naturally falls on the shoulders of the banks. It is much more flexible, and the economic effect is much betters, to adopt the form of bank credit on a compensation basis relying on economic measures in comparison with the form of financial appropriates that are gratutions. The reform of the banking system comprises reliance on bank credit to provide funds for all the circulation capital of the enterprises, for the needs of the old enterprises in tapping potential, renovating and restructuring as well as the medium and small-scale capital investments appropriated from budgetary expenses that can be recovered in a short time. The government financial authorities will be mainly responsible for strategic investment, the appropriations for state defense, administrative expenses, large-scale energy and transportation facilities, geological exploration as well as other major construction programs. In this manner, it is possible to overcome the disadvantage of providing funds through gratuitous government appropriations for the needs of all expanded reproduction and those for the majority of simple reproduction. This is beneficial to providing solutions to disputes among certain departments contending for projects and investment without due attention to economic effect, giving rise to great loss and waste of funds. This also alleviates the burden of government finance. At present, our government finance is under heavy loads. The final outcome can only be the appearance of deficist, followed by overdrafts and borrowing from banks and pressure on the banks to issue more bank notes. This practice of filling financial gaps by bank credit in the long run is no way to work out solutions for financial problems. Moreover, this also gives full play to bank credit's function as an economic lever, putting these funds into circulation at a cost and making the enterprises operate on strictly controlled budgets and pay attention to efficient use of funds. Of course, it should be noted that the size of total bank loans and their general direction of allocation should be used the control of state planning so that the scale of capital construction will not be expanded.

//Second, banks should be managed as enterprises with autonomy to carry on their operations.//

Banks as financial enterprises should be run as enterprises. This is to say, they should be run according to economic methods to meet the requirements of enterprise management in order to greatly enhance the quality of bank work. The following are the main points: (1) We must work in accordance with the objective law, organize and make use of the funds in the most efficient way and change the practice of running the banks with undue administrative means. Banks at all levels should be run independently, and be responsible for their own profits and losses, and interest must be paid for the use of the allocated funds as well as for loanable funds transferred between banks. (2) Motivation must be given to the masses of staff and workers to arouse their initiative and creativeness as well as their voluntary concern about the economic well-being of the organization they work for. This requires not only the strengthening of our political and ideological work, but also the setting up of certain economic systems and the adopting bonus system, and on a trial basis implement the system of profit-sharing and assigning full responsibility in regard to disbursement of expenses so that the interests of the state, the collective and the individual are all looked after, putting the performance of operation in direct correlation with the interests of the enterprises and those of the staff and workers. This will make every staff and worker pay attention to the quality of their work and economic efficiency. (3) Play must be given to the leverage function of interest. Bank interest of socialist countries is a part of the social net income. It represents the interrelations of the economic interests of the state (through the banks), the enterprises, and individuals in regard to credit funds accumulation and allocation. However, the present interest rates of our enterprise deposits and enterprise loans are on the low side, and the loan interest rate of the banks and that of savings deposits are linked in the reverse order. Moreover, our interest rate brackets are few in number. Once a rate is fixed, it remains so for years. None of this is suited to the requirements of running banks as enterprises. Therefore, the interest on deposits and loans should be increased, and differential for interest rates and floating interest rates should be put into practice. (4) Banks should have autonomy to carry on business operations. The state only specifies the direction of the bank loan allocation, the policy for making loans and the size of total bank loans. As to the conditions governing each loan, its amount and maturity, the banks make the decision according to credit policy, and the leading organizations as well as their supervisory institutions must not unduly interfere. With autonomy the banks must also bear the loan risks and assume the relevant economic responsibilities. (5) There must be advanced management controls. An information system must be set up for the banks which should join the trade associations of relevant industries. Thus, a national economic information network can be set up, the management activities of countless economic entities can be known, and a reliable basis for rational organization and employment of monetary funds can be provided. In the meantime, computers are to be gradually installed and advanced computerized control is to be adopted so that punctuality, speed and accuracy may be achieved in connection with the onerous daily operation dealing with tabulation of data, statistics, accounting, receipt and payment of money, and so on. Finally, in order to carry out enterprise management for the banks, there must be a team of cadres with a good knowledge of the theory and practice, as well as working ability, of financial operations. Correspondingly, a system of job evaluation, rewards and penalties, promotion, conferment of proper titles, and so on, must be set up to facilitate the discovery and training of qualified personnel, and to achieve the end of selecting outstanding candidates to the various posts and to give full play to their talents.

//Third, establish a scientific monetary management system.//

In the past 30 odd years, for quite a long time, we have had only one bank--the People's Bank of China. It assumes not only the functions of a central bank, but also operates the banking business of specialized banks. Now, two specialized banks are in operation. The Agricultural Bank of China has been restored, and the Bank of China set up. The People's Construction Bank of China has been allowed to add the operation of loan facilities instead of being strictly restricted to the operation of allocating funds for capital construction of our country as in the past. In some localities trust investment companies and other financial institutions have been established. What should the interrelations among these institutions be? The People's Bank of China is the central bank, or the bank of the banks. It is responsible for the overall planning and coordination of the activities of the specialized banks and the other monetary institutions. According to the relevant stipulations of our country, the central bank is also responsible for the issue of bank notes, the control of currency circulation, the formation of monetary policies, the setting of the standard interest rate, the drawing up of the plan for national credit allocation and reimbursement and that for bank note issues, the control of the monetary market, the formulation of a monetary settlement system, the coordination of national settlement operations, acting as a financial trustee for the state, the execution of collecting reserves from the specialized banks, and so on. For the specialized banks, within the sphere of their specialized duties, they should operate their business independently, each executing its own function and each assuming its own responsibilities. Between the central bank and the specialized banks, there should be a basic division of duties, but certain overlapping is allowed. This is beneficial to mutual help in work and the advancement of business operations. In the case of surplus and deficit of funds among the specialized banks, they are allowed to lend and borrow among themselves to smooth monetary circulation, provided that economic measures are adopted and interest payment is assured. The banks at the basic level are at the forefront of the monetary system. Every monetary policy and business activity is executed and developed through them. Therefore, the performance of the banks at the basic level is the key link in achieving the full and proper play of the various functions of banks. The superior banking authorities should strengthen their leadership in respect to the basic level banks, but there should not be excessive interference or control so tha the basic level banks may have their own authority and responsibilities and be able to develop various business operations on their own in the light of actual local conditions. Among the banks, a certain degree of unification should be maintained. At the same time, there should be relative independence. There is both specialization and cooperation, forming an integral socialist monetary system.

In short, reform of the banking system is a very complicated task. As banks comprise an integrated economic section, their reform will touch upon every economic department and entity, involving strict compliance with policies and bringing broad contacts. Consequently, a steady pace must be maintained for the reform and "each stone protruding above the surface of the water should be touched before stepping on it while crossing the river."

(III)

The purpose of reforming the banking system is to implement the "eight-character" policy, and to give better play to the functions of banks, and for the present moment in particular, to serve the readjustment of our national economy. Can this end of of reforming the banking system be achieved? The answer is, certainly.

The reason is that in the socialist commodity economy of our country, the activities of money and credit have spread into the realms of production, circulation, distribution and consumption of the country. The banks as special enterprises dealing with money and credit, having a broad range of contacts, with branches all over the country and with business connections with the enterprises of all sectors, play the important role of "regulating the whole country with an economic life organized in the socialist fashion" (Lenin's words). This function the banks have of regulating the economy is realized by employing economic measures such as money, credit, interest, and so on.

First, regulate the economic proportions of agriculture, light industry, heavy industry, accumulation, consumption, the internal structure of industry, and so on, by expansion and contraction of credit and by adjusting the needs and flow of credit. As we know, the characteristics of bank credit are the collection of idle and dispersed funds by paying a reward from various sectors of the society and the reloaning of these funds to borrowers, thus putting them back into circulation to exercise their function. Therefore, the banks can achieve the end of regulating the economy by selecting the borrowers of their loans, by giving favorable or restrictive terms for loans and by putting the loanable funds to rational use according to the requirements of the economic readjustment guideline. For example, in the case of the light and textile industries which need less investment but show quicker results and yield larger earnings, by supporting them with bank credit the banks can stimulate their production growth, thereby supplying the market with more marketable and needed products, and withdraw part of the currency from circulation. For goods in excessive supply which are already overstocked, overstocking can be reduced and the capital construction from shortened by contracting credit which will limit production. As for those products which compete for raw materials and fuel with advanced enterprises and which suffer from high cost of production, inferior product quality and poor sales, the banks will stop giving them loans. This will accelerate the process of closing, suspending, merging, and shifting [to other modes of production]. All these measures are conducive to the successful implementation of economic readjustment.

Second, the basic balance between purchasing power and commodity supply can be accelerated and the stability of prices and the economy can be achieved by regulating money circulation and controlling bank note issuance. The volume of money circulating on the market is an integrated economic indicator, giving a sensitive reflection of the problems in economic proportions and prices. As our experience in the past 30 odd years shows, with excessive currency on the market, the fundamental reasons for price instability are these: the excessive length of the capital construction front and the enormous government deficits. This is what we ordinarily refer to as "capital construction putting pressure on the financial authorities, which pass on the pressure to the banks and the banks end up by issuing more bank notes." Consequently, the control of bank note issuance and the regulation of monetary circulation according to the monetary circulation law that the circulation of money must adapt itself to commodity circulation are important measures for price stability and economic stability.

Third, promote economic efficiency and enliven the economy on the part of the enterprises through the economic leverage of interest rates. For example, for those sectors the development of which is much needed by the country such as agriculture, light and textile industries and the energy industry, preferential interest rates should be extended to expedite their development. Conversely, for products that suffer from high costs, inferior quality and huge overstocking, the banks will require higher interest rates to urge the enterprises to strengthen their management, lower their costs, improve their quality, lessen overstocking, and enliven supplies and funds.

In short, the function of the banks in regulating the economy and stimulating economic readjustment is quite obvious. Of course, in regulating the economy, the banks employ not only economic measures such as credit, money, and interest, but they also use the administrative authority conferred on them by the state such as the control of cash, the management of wages, and the management of foreign exchange in order to directly control the economy according to the policies of the state, under the guidance of the local party committee and government and in cooperation with the departments concerned to make good their economic readjustment duties with their combined efforts.

FINANCE AND BANKING

INCREASES IN INDIVIDUAL BUSINESS LOANS SEEN

Xian SHAANXI RIBAO in Chinese 10 Jul 81 p 2

[Article from Commercial Credit Department, Provincial People's Bank: "Vigorous Support to Collective and Individual Business Through Liberalization of Credit Policies by Provincial Branches of People's Bank"]

[Text] Shaanxi provincial branch banks and subordinate organizations of the Chinese People's Bank have liberalized policies and abolished restrictions in active support of the revival and development of collective and individual businesses.

1. Expansion of scope of loan grants. Loans issued since last year up until the end of April this year to collective and individual customers amount to 11.01 million yuan, 26.5 times the amount as of the end of 1978. Since last year, the Xida Street Cooperative Clothing Store in Xian has borrowed at 21 different times a total of 2.58 million yuan. Its volume of business has increased from an average monthly 32,000 yuan to 92,000 yuan, and it has accumulated 99,000 yuan after taxes. Last September the Xianyang Municipal Service Corps for Youths awaiting employment borrowed 30,000 yuan, and had a monthly business income of almost 20,000 yuan. It was able to wipe out the entire loan within 2 months.

2. Support of fund requirements for newly added outlets. Last March, when children of the workers and staff of the Xian Municipal Knitgoods Company organized the Julin composite store, they needed 300,000 yuan of start-up funds. Except for 60,000 yuan, which the company provided itself, the remainder consisted of bank loans. By year's end, this store had already accumulated 102,000 yuan, and for the first 4 months of this year, it realized an additional 49,000 yuan of profits. The Zhangjiacun Cooperative Store in Xian added 39 staff and employees last year at two new outlets. Bank loans of 35,000 yuan helped the businesses start up very quickly.

3. Liberalization of limitations on settlement of accounts, support to collective businesses in expansion of channels for bringing in goods, and procurement from elsewhere of readily marketable goods. During this April, the Jiefang Road Office in Xian handled, on behalf of the School Graduate Composite Shop of the Railway Bureau Workers Service Company, seven collections of funds for goods from Shanghai, Wuhan, and Baoji amounting to more than 160,000 yuan, amounting to 70 percent of the store's total goods received for the month.

4. Permission to individual businesses to open accounts at the banks, handling settlement of accounts, and issuing loans. Xian resident Song Wemxiang [1345 2429 4382] started a family sewing shop for which the bank gave him a loan of 550 yuan to help him buy a lockstitching machine to expand his business. As a result of the increase in his earnings, he has repayed the debt ahead of time.

5. Assistance to enterprises in their fiscal management. Banks in Ziyang and Xianyang have taken the initiative in helping school graduate shops and service crops for youths awaiting employment to set up bookkeeping and accounting assistance personnel, to keep accurate accounts, to do a good job of accounting, and to increase profits.

BRIEFS

XINJIANG SAVINGS DEPOSITS--There has been a rapid rise in the Xinjiang peasants' and herdsmen's savings deposits. By the end of this June, their total savings deposits amounted to over 130 million yuan, an increase of 35 percent as compared with the same period of last year, thus topping the highest level in history. [HK190706 Urumqi Xinjiang Regional Service in Mandarin 1300 GMT 4 Aug 81]

HAINAN PREFECTURE TRADE CONFERENCE--Hainan Li-Miao Autonomous Prefecture recently held a conference on finance and trade work. The conference demanded that the autonomous prefectural finance and trade front eliminate the influence of leftist ideology, gradually implement the various economic responsibility systems, quickly turn loss to profit and enliven finance and trade work. The conference pointed out that the main problem was that the finance and trade front's amount of procurement has dropped and its expenses have increased this year. The profits derived from commerce in the autonomous prefecture were 24 percent less than in the first half of last year. The state-run catering trade generally incurred losses. The conference demanded that the finance and trade enterprises conduct large-scale inspection of financial and economic discipline within this year and special persons be assigned to handle economic cases as quickly as possible. [HK190741 Haikou Hainan Island Service in Mandarin 0330 GMT 2 Aug 81]

QINGHAI TAX EVASION--About 57 percent of the enterprises in Qinghai Province were involved in tax evasion and fraud in the past year. Some units include entertainment expenses as production costs. During an investigation conducted throughout the province, over 6.2 million yuan of taxes were found to be unpaid or evaded. By early July, 1.81 million yuan of evaded taxes had been handed over to the state. [SK201024 Xining Qinghai Provincial Service in Mandarin 1100 GMT 19 Aug 81]

HEILONGJIANG SAVINGS DEPOSITS--Harbin, 10 Aug (XINHUA)--According to figures released by the Heilongjiang Provincial People's Bank, by the end of July Heilongjiang's urban and rural savings deposits totaled 2.24 billion yuan, an increase of 42.3 percent over that at the same time last year. ENERGY CONSERVATION SAID A MAJOR PART OF ECONOMIC READJUSTMENT

Beijing RENMIN RIBAO in Chinese 9 May 81 p 2

[Article by Bao Guangqian [7637 0342 0467] and Du Hongyu [2629 4767 7183]]

[Text] In a situation in which the contradiction in energy supply and demand is so outstanding, in addition to increasing the production of energy as much as possible, the most urgent business of the day is to engage in energy conservation in all forms and to build up the habit of energy conservation in general.

Seek Energy in the Form of Technological Renovation

The greater majority of China's enterprises use antiquated energy equipment that has a low thermal efficiency and consumes excessive energy. Only a small number have newly manufactured energy equipment that is efficient and of a high performance type. Of the more than 28,000 items of energy equipment being manufactured today, more than 15,000 items are old models. And many people still entertain the thought of basic construction in order to increase production and are busily building new plants and installing newly built old-model equipment, when there is a serious shortage in the energy supply. A number of comrades who are engaged in energy-related research work consider that the idea of those who hold that in order to double production the facility must also be doubled in scale is onesided and quite out of touch with the reality of China's energy production situation. We must establish guidelines for the future as follows: develop technological renovation centered around energy conservation; systematically replace antiquated facilities which waste energy; and remove oil and coal from the hungry tiger's mouth, in order to significantly save energy and achieve a good economic effect.

Comrades who are engaged in work related to capital investment in basic construction have made some calculations. Due to the shortage of energy, approximately 30 percent of the existing production capacity today cannot be utilized. Specifically, there is a shortage of approximately 10 million kW of electricity, equivalent to more than 20 million tons of standard coal. If we start out with the technological renovation of equpment which wastes energy by undertaking the remodeling of medium- and low-pressure power generating assemblies and old boilers together with some other measures, we can improve the energy shortage situation in a relatively short period. Based on an estimate made by the concerned department, if the technological renovation is done well, the energy shortage that exists today can be basically eliminated in 5 years with an expenditure of only 3-4 billion yuan. The time and money thus expended will be shorter and less than what would be needed if we were to invest in coal mine construction in order to increase energy production. It is evident from this that conserving energy and increasing production of energy are both equally important.

Wasting less energy is an important index of the advancement of the national economy and technology. The very process of technological renovation for the purpose of energy conservation is also the process of raising the technological standard. Therefore, in order to make progress in China's socialist modernization, technological reform ought to be an important starting point. A number of comrades advocate that w must, over a relatively long period, emphasize research in energy-saving technology, making the development of energy-saving technological renovation one of the most amjor subjects of research, and during the period of national economic readjustment, at least, we must properly concentrate our financial and material resources on the remodeling and replacement of energy equipment with low efficiency.

Build Up a Habit of Energy Conservation in General

Since 1964, Troop No 51112 of Beijing garrison district has collected ashes and residue from the furnaces and chimneys of factories in the urban area and used them for cooking purposes as a substitute for coal. They have bought almost no coal in the past 16-17 years, thus saving more than 23,700 tons of coal. The exemplary deed of Troop 51112 is very moving and also thought-provoking.

Since liberation, China's energy resource development has made relatively rapid progress. In 1979, 63.5 million tons of raw coal were produced, 20 times the yield in the early days of liberation; 106 million tons of crude oil, more than 880 times; 14.5 billion cubic meters of natural gas, more than 1,300 times; and 5.01 billion units of hydroelectric power, more than 60 times. It was not easy to reach today's standard (in such a short period of time), a feat not many other countries of the world have achieved. Nevertheless, China's energy supply still does not satisfy the demand and the reserve is low. We must protect our energy resources as carefully as our liberation army soldiers did.

China's energy utilization rate is very low and the waste is very great. In 1978, the energy utilization rate was 57 percent in Japan; 51 percent in the United States; and 40 percent in the Western European countries. It was only 30 percent in China, so 70 percent of the heat was wasted. Raising the energy utilization rate by just 10 percent would be equivalent to an effective increase of 60 million tons of coal a year. This kind of calculation may not be convincing enough, but there is no excuse for not being able to achieve today a standard which was reached in the pst. Between January and November last year, among more than 500 key enterprises belonging to the metallurgy, electric power, petroleum, and coal departments, 30 out of 74 indexes related to energy and raw material consumption were found to be below the highest historical standard, and there were 24 items whose energy consumption indexes were higher than those of the same period of the previous year. Electric power consumption per ton of cotton during the first half of last year was 60 kWh more than the same period the year before, and 27 kWh more electricity per 10,000 meters of cotton cloth. This phenomenon is far from normal. There are many reasons why energy waste is so serious in China today. One of the more important reasons is that the habit of energy conservation has not yet been established in our society in general, and our enterprises in particular. If every department, every unit, and every enterprise will, following the steps of Troop No 51112, take the leading role and work with the masses in attaching great importance to energy conservation, constantly renovating the energy equipment, and encouraging and promoting energy conservation by implementing appropriate policies and regulations, then work related to energy conservation should be able to present a new and bright situation soon.

Energy-Related Legislation Must Be Enacted

Developing energy conservation education and making a list of what ought to be done in order to be able to conserve energy are necessary and effective measures. However, these measures may not be effective for some districts and units. Since 1972, our government started replacing low-efficiency boilers and cut down production of boilers of smaller capacity and less efficiency. But there are many counties, communes and brigades where production of less efficient boilers well in excess of the planned number is still going on. According to the statistics, there are more than 400 such boiler plants in the four provinces of Henan, Shandong, Liaoning, and Jilin. The boilers manufactured by a number of small boiler plants of the Chegang Commune in Fu County, Liaoning Province, are not only low in thermal efficiency but also high in fuel consumption. They also break down quite frequently. Similar problems exist in the field of automotive vehicle manufacturing and utilization. Last year, the government planned to manufacture only 120,000 automotive vehicles based on the need for national economic readjustment and conservation of energy. However, many automotive vehicle plants did not produce according to the plan. More than 90,000 automotive vehicles in excess of the plan were manufactured, contributing to the consumption of an additional 450,000 tons of oil a year, which amounted to half of the oil conserved by all oil-consuming machines, including automotive vehicles. Generally speaking, the transport efficiency of automotive vehicles not belonging to the transportation department is only approximately two-thirds that of those that do belong, and they also consume 30 percent more oil. In spite of this, for a long time the share of automotive vehicles belonging to the transportation department has been smaller than those not belonging. There are more than 1.1 million freight-carrying automotive vehicles nationwide. Of these, more than 80 percent do not belong to the transportation department, while only 13.4 percent do belong to the department.

The reality that the supply does not satisfy the demand and that the energy waste is great demands enactment of a series of legislative measures. For example, production and utilization of boilers and automotive vehicles ought to be controlled by law: boilers whose thermal efficiency is below standard may not be manufactured; automotive vehicles manufactured according to the plan must satisfy a certain fuel-efficiency (mileage) standard: those which fail to meet the standard may not be manufactured, and they may not de delivered even if manufactured. The greater majority of automotive vehicles, especially freight-carrying vehicles, must by law be assigned to the transportation department. The useful life and the retirement standard for boilers and automotive vehicles must be spelled out, and those which are retired may only be returned to the furnace, never resold or repossessed.

Energy conservation has a decisive effect on our national economic readjustment. We must attach great importance to it and treat it as an important matter. We believe that if we can take various measures to reform the economic structure and technology, if we can formulate energy prices, energy laws, and energy policies which will encourage the masses to conserve energy and thus strengthen our energy management, we should be able to build good habits of energy conservation by individuals, enterprises, and the society as a whole.

READJUSTMENT OF STEEL INDUSTRY

HK230930 Beijing JINGJI GUANLI [ECONOMIC MANAGEMENT] in Chinese No 6, 15 Jun 81 pp 3-6

[Article by Investigation and Research Office of the Ministry of Metallurgical Industry: "Conscientiously Sum Up Experiences and Do a Better Job of Readjusting the Iron and Steel Industry"]

[Text]

I

Over the past 2 years, the vast numbers of workers in the iron and steel industry have implemented the principle of readjusting our national economy, done a great deal of work and achieved relatively great success. A fine situation in iron and steel production, seldom experienced since the founding of the PRC, has appeared. This fine situation is markedly reflected in the following five changes.

1. Now that output is determined by sales, the industry has begun to gear itself to the needs of the light industry as its market, and the composition of products has undergone a preliminary change. The output of various products urgently needed by the state, such as wire rods, small steel products, thin plates, welded pipes, strip steel, medium-sized products and various steel products in short supply, reached 18.64 million tons in 1980, an increase of 6.38 million tons over 1978. The proportion of such products in the total annual output of steel products increased from 55.5 percent in 1978 to 68.4 percent in 1980.

2. There has been economy in the use of energy resources and output has increased. The consumption of energy resources has kept on falling. In 1980, steel output increased by 5.3 million tons compared with 1978, but the total energy consumption of the iron and steel industry decreased by 2.8 million tons of standard coal. In key iron and steel works, the combined consumption of energy resources per ton of steel decreased from 1.77 tons of standard coal in 1978 to 1.47 tons in 1980.

3. Economic results have improved and profits have grown rather substantially. In both 1979 and 1980, the profits of the iron and steel industry increased by around 1 billion yuan over the previous year. For the medium-sized and small iron and steel works, there was a net loss of 638 million yuan in 1978, a net loss of 292 million yuan in 1979 and a net profit of 486 million yuan in 1980.

4. Because some enterprises have been assigned greater decisionmaking power, they have acquired internal economic motive force, their ideas about operations have changed, and their concepts of the market, of competition and of serving consumers have been strengthened. Consequently, the state has been able to collect more revenue, the enterprises have retained larger amounts of profits, and individuals have earned a higher income.

5. After rectification and the strengthening of basic work, the standard in running and managing the enterprises has improved. Five joint iron and steel works, namely the Anshan Steel Works, the Benxi Steel Works, the Capital Iron and Steel Company, the Panzhihua Steel Works and the Taiyuan Steel Works, have been appraised as outstanding units in enterprise management by the Enterprise Management Association of China.

However, at present, there is serious disproportion in both the relations between the iron and steel industry and other sectors of the economy and the relations between various links in the iron and steel industry itself.

The iron and steel industry is a basic industrial sector which provides various steel products to various sectors of the national economy and supplies steel products for national defense construction. It is a sector which serves others. It is indispensable to national economic development, improvement of the peoples livelihood and the strengthening of national defense. Since the founding of the PRC, the iron and steel industry has made contributions in these respects. However, over many years, it has been placed in an inappropriate position because of the guiding idea "take steel as the key link." On several occasions, forward leaps were launched to boost the iron and steel industry. Our national strength was not considered and no attention was paid to the coordinated development of various related links of the economy. Consequently, the iron and steel industry did not develop healthily, and it even became a drag on the national economy. During the first 2 years after the smashing of the "gang of four," the economic situation was erroneously appraised and "leftist" errors were committed. A grandiose plan to develop the iron and steel industry, which was divorced from actual conditions, was worked out. In particular, the rash construction of the Baoshan Steel Works and the import of foreign equipment on a full scale led to voracious consumption of funds, displaced a large number of other projects and aggravated the disproportion in the national economic relations. According to the principal leading comrades of the ministry at the recently convened national work conference on metallurgy, after the Party Central Committee had put forward the principle of readjustment, the leaders of the ministry did not deeply understand the necessity and urgency of readjustment, were slow to acquire awareness, and did not grasp it vigorously, so that the overall readjustment of the national economy was affected.

The grave disproportion in the iron and steel industry is reflected mainly in the following facts. The vareity and quality of iron and steel products do not comply with the needs of various sectors of the economy. In particular, steel products needed by light industry, by the market or for the peoples livelihood are still unable to satisfy consumers needs in both variety and quality, and a considerable proportion of such products must still be imported. Mining lags far behind smelting, so that it is difficult to fully bring comprehensive production capability into play. Grave disproportion also exists in the relation between "bone" and "flesh."

II

To do a better job of readjusting the iron and steel industry, we must clear away very satisfactorily the influences of "leftist" ideology on this industry. We should note that the above-mentioned situation of grave disproportion in this industry is not a recent phenomenon. It has been formed over many years. The comrades who attended the recent work conference on metallurgy have conscientiously summed up past experiences and drawn the following major lessons.

1. To develop the iron and steel industry, we must clearly understand our national conditions, subordinate the industry to the overall situation, place the relation between this industry and the overall national economy in a correct position and overcome blindness. In planning new construction projects, we must follow the principle of working within our capabilities and fully consider their feasibility in the light of our national strength, so that the development of the iron and steel industry may be coordinated with our national economic development.

2. We must put the basis and emphasis of our work on the existing foundation, fully bring the role of the existing enterprises into play and take the road of emphasizing quality, increasing product varieties, reducing consumption and boosting earnings.

3. We must pay great attention to internal equilibrium in the iron and steel industry, exploit our comprheensive production capability, conscientiously solve the problem of disproprotion between smelting and mining and between production and livelihood, and ensure the healthy development of the iron and steel industry.

4. We must satisfactorily organize production, with key emphasis on increasing product varieties, improving quality, economizing on energy resources and reducing consumption, and thus serve various sectors of our national economy. In particular we must serve the people in providing food, clothing, housing, transport facilities and other daily goods.

5. We must respect science, strengthen investigation and study, and vigorously work according to objective laws. In capital construction, we must satisfactorily complete the earlier stages of the work and work strictly according to the procedures of capital construction. We must work out several schemes for each project and choose the optimum one by comparing results of investment. In exercising leadership over production, we must pay attention to the different characteristics of various industries. We must not "treat everything the same way regardless of circumstances" or even just make a terrific din.

6. We must conscientiously implement the mass line, fully carry forward democracy and earnestly consider different opinions. Making decisions on major projects must involve study by experts and joint consultation between leading cadres and experts. We must not allow a minority of people to have all the say.

III

During readjustment, the iron and steel industry must change over to the path of serving the technological transformation of our national economy and providing various materials which are up to standard for producing durable consumer goods. We must further readjust the composition of products, the internal proportions of the industry and its organizational structure. We must satisfactorily tap the existing enterprises' potential, carry out innovations and improvements and raise economic results. Specifically, we must satisfactorily grasp the following several tasks:

1. Further reduce the scale of capital construction, rectify the orientation of investment and improve the results of investment.

Over the past 2 years, investment in the iron and steel industry has been cut rather substantially. In the coming several years, investment will not increase substantially. Therefore, we must consciously subordinate ourselves to the overall situation and do a good job in using the limited funds. In the future, the orientation of investment in the iron and steel industry must be in the first place use of investment funds to develop mining, increase product varieties, improve quality, develop measures to help economize on energy resources, protect the environment and enhance safety in production. We must also try our best to set aside some investment funds for developing education and scientific research and providing workers with living quarters. We must assimilate the lessons of past experiences of emphasizing capital construction at the expense of production so that in the future, even in undertaking projects involving increasing product varieties and improving quality, we must also proceed from the existing foundation as far as possible. We must in the first place undertake those projects which require a small amount of investment funds and produce quick results, boost the production of meters and instruments for calculation, inspection, testing and control, and set up processes for the earlier or final stages of production which are essential to ensuring quality. We must conscientiously clean up those projects whose design or technology is not up to standard or those in which investment produces poor results. As to those projects which have been suspended or postponed, we must satisfactorily perform various residual tasks, carefully maintain and protect the equipment involved and strive to reduce losses to the minimum. In the case of projects under construction, we must impose stringent demands, ensure quality, complete them punctually, try our best to economize on funds and improve the results of investment.

2. We must gear the industry to the ever-increasing demand of our population of 1 billion and our 800 million peasants for steel products which are used in connection with their consumption of food, clothing, housing, transport facilities and other daily goods. We must further change the composition of products and improve product quality.

Currently, the iron and steel industry must attach prime importance to increasing the output of steel products needed by the market in light industrial products and agriculture or needed for the people's livelihood and civil construction works. We must conscientiously conduct investigation of market needs, strengthen market forecasting, take the initiative to consider consumers' opinions, and take the consumers' needs as a motive force to improve product quality or increase product varieties. We must strengthen product research, vigorously develop technological services, understand the production techniques adopted by consumers, and take the initiative to help consumers choose and use superior materials. The countryside is a vast market. At present, the financial conditions of the peasants in many localities have improved, and building houses, manufacturing handcarts and small farm equipment and so on require large quantities of steel products. We must strengthen investigation and study and adopt measures to increase the output of steel products for agricultural use.

We must devote our greatest efforts to increasing the output of thin plates and strip steel. The manufacturing of certain light industrial products, such as bikes, washing machines, electrical appliances for civil use, enamelware and so on, require large quantities of thin plates and strip steel. Thus, such steel products are currently in the severest shortage. We must also vigorously increase the output of wire rods needed for manufacturing iron wires and nails.

Enterprises with favorable conditions must also vigorously expand the variety of their products, directly produce some consumer goods according to market needs and offer them to the market.

As for those products in excess supply, relatively large quantities of which are kept in stock at present, even if they are really needed by the market, we must reduce their output and inventories according to the principle of clearing the warehouses of excessive stocks before further production.

3. We must try all means to economize on energy resources, take this as a strategic task and vigorously do a good job in grasping it.

Developing our country's iron and steel industry can only be based on low energy consumption. This year, the quotas for energy resources allocated by the state to the iron and steel sector according to plans for iron and steel production have shown a decrease of around 8 million tons of standard coal. The iron and steel works must further reduce energy consumption on the basis of last year's achievement in reducing consumption.

All iron and steel works must continue to strengthen energy resources management, formulate stipulations on economizing energy consumption and fixed quotas for energy consumption for all major subprocesses and conduct rigorous checks according to the set quotas. In the light of various enterprises' actual conditions, we must continue to popularize those experiences in economizing energy consumption which practice has proved to be effective, such as fine screening and repeated grinding of ores, sintering of low-carbon-content raw materials, using large lots of materials and high blast temperatures in the blast furnace process, energy-economizing operations for the open hearth furnace, raising the temperature of hot ingots in roughing down, and so on. We must superbly organize production and must be rational in starting or stopping the operation of equipment. We must integrate the economizing of energy resources with technological transformation. In particular, we must satisfactorily grasp measures to economize on oil, readjust the energy consumption pattern of the iron and steel industry and substitute coal for oil. For those local iron and steel works with high energy consumption, we must appropriately close them, suspend their production work, merge them or shift them to other types of production.

An important task in economizing energy consumption by the iron and steel industry is to vigorously lower the iron to steel output ratio. Because at present, around 60 percent of the total energy consumption by our country's iron and steel industry is attributable to processes prior to iron smelting, lowering the iron to steel output ratio is of great significance to economizing on energy resources. In 1980, this ratio was 1.03 in our country, approximately 0.3 higher than in Japan, West Germany or the Soviet Union. An important reason for such a high ratio for our country is that we produced large quantities of pig iron for casting purposes. Last year, our country produced over 9 million tons of pig iron for casting, whereas in 1978, the combined total output of the pig iron for casting of the five major steel-producing countries, namely the United States, Japan, West Germany, Britain and France, was merely 5.64 million tons. In conjunction with the metallurgical sector, the machine-building industry, construction industry and so on must substitute welded articles for cast iron articles to reduce the consumption of pig iron for casting. We must also strengthen the collection and utilization of scrap steel.

4. We must tap the potential of existing mines, vigorously grasp the building of new mines which are being opened up and place the readjustment of mining in an important position.

The problem that mining lags behind smelting is basically due to emphasizing smelting at the expense of mining. This problem is also due to the fact that in building mines, we did not work satisfactorily according to objective laws governing mining, did not build up comprehensive production capability in earlier periods and did not fully utilize natural resources.

We must vigorously grasp building mines which are being opened up and tap the potential of existing mines so that the results of investment may be realized as soon as possible. We must vigorously grasp the readjustment of weak links in mining and do a good job of filling the gaps and forming complete sets of equipment for mining and ore dressing. We must continue to readjust the relationship between excavation and mining-with-filling, and fully bring the comprehensive production capability of the existing mines into play.

We must attach special importance to satisfactorily grasping various kinds of work at the open pits, which yield 90 percent of the total output of ores. Thus, we must strengthen the management of stopes and equipment. In particular, we must satisfactorily grasp transportation by truck, which is a weak link. We must improve the supply of spare parts and the maintenance and repair of equipment. We must do a good job of building roads to serve the mines. We must raise the efficiency of comprheensive excavation work, increase the rate of extraction and reduce the rate of ore dilution.

5. We must vigorously do a good job of enhancing safety in production, vigorously tackle pollution and improve the environment, and gradually solve the problem of disproportion between "bones" and "flesh."

All iron and steel works must continue to implement the 10 measures put forward at the work conference of the metallurgical industry on safety convened in October last year, proceed from analyzing industrial accidents, conscientiously sum up experiences and adopt various measures in the light of the first aims. The elimination of major hidden dangers must be included in readjustment plans and we must vigorously tackle these dangers. We must actively prevent and tackle pollution and improve the environment. We must deal with these problems step-by-step according to the principle of proceeding from easier tasks to more difficult tasks and from elementary levels to advanced levels. We must include tackling the pollution problem in the production process, strengthen production management and technical management, integrate tackling the pollution problem with the transformation of enterprises, improve technology in combination with large-scale or medium-scale repair as well as renewal and transformation of equipment, and create conditions for further tackling the pollution problem by vigorously launching scientific research on and monitoring of the environment. We must continue to satisfactorily grasp the building of workers living quarters and the enhancing of collective welfare and gradually improve the workers' housing and living conditions.

6. We must improve the running and management of enterprises, improve economic results, increase income and cut expenditures.

Over the past several years, the profits of the iron and steel industry have kept on increasing. However, the level of profits is still rather low. The rate of profits, either as a percentage of investment funds or of output value, has been lower than past records. This year, the output of iron and steel is being reduced. The proportion of some more profitable, superior quality steel products in the total output has also dropped rather substantially. This is a new problem due to readjustment. The iron and steel works must face realities, improve their work, mobilize the masses, overcome difficulties, and vigorously try to reduce the decrease in income to a very low figure or even to zero in the face of a decrease in output. Enterprises with favorable conditions must also try to achieve an increase in income despite a decrease in output.

We must continue to improve overall economic accounting. We must mobilize the enthusiasm of the vast numbers of workers so that all workers will be able to manage financial affairs as masters. We must further strengthen management, improve the running of enterprises, open up many new ways of endeavor and seek a large number of sources of funds. We must reduce consumption, improve product quality, change the composition of products, produce new categories of products, reduce the quantities of inventories, cut expenditures, lower production costs and improve economic results.

7. We must do a good job of grasping the readjustment of organizational structures and gradually effect various forms of integration.

We must vigorously grasp the readjustment of organizational structures and gradually put an end to the phenomenon of enterprises being "large and complete" or "small and complete." Such a readjustment also amounts to a kind of reform.

At present, in the iron and steel industrial system, many forms of economic conglomerations have been organized. We must actively support all kinds of reorganization and integration that are beneficial to the overall situation. In organizing various forms of economic conglomerations, we must proceed from actual conditions and suit measures to local conditions. Integration may be loose or close and horizontal or vertical. In carrying out readjustments of organizational structures, we must pay attention to proceeding from helping the localities achieve the best economic results. Such readjustments, which involve the integration of large, medium-sized and small enterprises, must comply with the principle of cooperation among specialized enterprises and the requirement that enterprises get organized. Moreover, we must pay attention to bringing the strong points of various enterprises in each category of production into play, carrying forward their strength and circumventing their weaknesses, and effecting integration among different categories of production.

The accomplishment of the readjustment of the iron and steel industry depends on the key factor of fully bringing the enthusiasm and initiative of the vast numbers of workers into play and continuously raising their standards in such things as ideology, political thinking, educational attainment, technology and ability to run and manage enterprises. Thus, we must strengthen ideological and political work and conscientiously do a good job of training workers. All enterprises must continue to do a good job of rectification. The key task is to satisfactorily grasp basic management work in a donw-to-earth manner. In particular, the enterprises must continue to pay attention to perfecting the system of personal responsibility, rectifying and strengthening the keeping of original records, statistical work, calculation, checking and testing, as well as doing a good job of management according to quotas.

Over the past 31 years, a relatively good foundation has been laid for the development of our country's iron and steel industry. There are a number of large or medium-sized key enterprises. At present, the conditions of some medium-sized local enterprises are much better than those of the Taiyuan Steel Works or Tangshan Steel Works at the time of the first 5-year plan period. We have a contingent of over 200,000 workers, which includes a number of engineering and technical personnel and cadres specialized in economic management. This contingent has fine traditions, as exemplified by the appearance of many heroic or exemplary personalities. Over the past several years, we have imported some new technology, which we can use for reference in further transforming the iron and steel industry. By studying the principles discussed at the recent work conference organized by the Party Central Committee, clearing away "leftist" ideology and summing up experiences, we will definitely be able to more satisfactorily implement the principle of readjustment and to make new contributions to the steady development of our national economy.

REFORM AMID READJUSTMENT

HK260921 Beijing JINGJI GUANLI [ECONOMIC MANAGEMENT] in Chinese No 6, 15 Jun 81 pp 33-36

[Article by the Shoudu Iron and Steel Company: "Fully Implement the Policy of Readjustment and Push One Step Further the Reform Favorable to Readjustment"--note passages within slantlines denote boldface type]

[Text]

(1)

The Shoudu Iron and Steel Company has been designated by the State Economic Committee as a trial-point unit in an effort to expand enterprise autonomy. In 1979, they implemented the system of profit retention. As from July 1980, this has been changed to the system of responsibility for one's own profits and losses which "substitutes tax for profit." Although the reform is still in its early states, it has already enabled the enterprise to free itself from its old straitjacket and thus become an economic unit with specific economic interests and powers of self-management, the ability to assume specific economic responsibilities and a relative independence. It has furnished definite preconditions for tapping potential within the enterprise and for pumping new lifeblood into it. All this is conducive to the implementation by the enterprise of the policy of readjustment and the livening up of microeconomics.

The reform has impelled the old enterprise to find a way of lowering consumption, raising efficiency and increasing profits. In the 2 years since setting up the trial points, we have, with our feet firmly planted on the present base, carried out a rational technological restructuring of the old factory and strengthened the overall management of the enterprise, causing the level of production, technology, administration and management to continuously rise. In 1979, of our company's 30 fixed technological and economic indices, 16 won first prize in competition with domestic enterprises engaged in the same trade. Of the 132 struggle targets laid down in 1980, 94 were reached and 36 won first prize within the country. The grade of concentrate powder, blast furnace capacity factor, coke ratio, converter capacity factor, average furnace life and iron ore consumption, the six norms most commonly used internationally for measuring the level of production technology in iron and steel enterprises, reached an internationally advanced level. As for the products of the Shoudu Iron and Steel Company, third-rate products were eliminated in 1979 and second-rate products were eliminated in 1980. Fifteen products, accounting for one-third of the total products, were promoted to top-grade products. Pig iron casting and concentrate powder won the state's gold medal for quality. High frequency electric welding tubes won the state's silver medal for quality. New improvements have been made to the composition of the products in the course of readjustment. Energy consumption has gradually fallen. The fixed energy consumption for the production of 1 ton of steel in 1978 was 1,247 kilograms of standard gas. This fell to 1,177 kilograms in 1979 and 1,121 kilograms in 1980, showing decreases in the 2 years of 5.6 percent and 4.7 percent respectively. Administration and management of production technology appeared to be at their best since the founding of the state 31 years ago.

Reform brought about a change in the management thinking of enterprise leaders and a change within the enterprises run by the broad masses of staff and workers. They no longer seek to merely finish the production plan, but they also strive for economic effectiveness, thus achieving a continuous growth in total industrial output value. In 1979 and 1980, they achieved increases of 9.11 percent and 11.73 percent respectively over the year before. The amount of funds appropriated per 100 yuan of output value continued to fall year by year. Profits showed a massive increase 3 years in a row. In 1978, profits showed an increase of 85.8 percent over 1977. In 1979, profits showed an increase of 22.4 percent over 1978. In 1980, profits showed a further increase of 23.6 percent over 1979. In a situation where assets consist mainly of mines and iron and less of the capacity for producing products capable of increasing profits like steel and timber, the profit margin in relation to assets reached 17.25 percent, an advanced level in a domestic iron and steel integrated complex.

On the basis of promoting increased enterprise output and income, the "three mores" have been implemented, taking into consideration the interests of all three parties. As far as the distribution of the enterprise's profits is concerned, the state got 180.65 million yuan in 1978, 213.11 million yuan in 1979 and 246.87 million yuan in 1980. In the 2 years since the implementation of trial points, state revenue rose by 66.22 million yuan. Income accruing to the enterprise was 15.72 million yuan (including the welfare fund and bonuses), in 1978, 19.04 million yuan in 1979 and 37.08 million yuan in 1980. In 2 years, it made an extra 21.36 million yuan. The ratio of the state's increased income to that of the enterprise was 3:1. Rewards and welfare due to the staff and workers showed a corresponding increase.

(2)

Under the new situation of readjustment, the problem of how to correctly handle the relationship between readjustment and reform remains one of primary importance as far as expanding the powers of trial-point enterprises is concerned. For the past 2 years, we have persisted in the full implementation of the eight-character policy. We have, with readjustment as the center and rectification as the base, made full use of advantageous elements of the reform to carry out internal readjustment and have reached the target of an overall increase in the various work spheres. Our basic method has been:

/1. To integrate the expansion of power with rectification, thus enabling the reform work of the enterprise to have a firm base./

We must first rectify the leading groups at every level according to the demands made by the four modernizations. We must promote to leadership posts at every level cadres who have emancipated their minds, are filled with revolutionary zeal, understand technology, are able to manage and are generally competent. The 30 factories and mines of the whole company, together with the engineering companies, have among them a total of 207 leading cadres. Of these, the 103 skilled cadres above the rank of assistant engineer account for 49.76 percent of the factories' management cadres. Of the 62 first and second class skilled hands in the factories and mines, apart from one secretary, and an old cadre who has just changed professions, all are quite familiar with technical work. A first-level leading group of the factories and mines generally does not exceed five or seven people at the most.

At the same time as rectifying the leading groups, we have treated the establishment and amplification of rules and regulations with the responsibility system as their core as the central link in the rectification of the enterprise, and have set up among the workers post assessment standards, including indices for output, quality and consumption, technical operation, equipment maintenance, accident control, civilized production, limitations on the amount of materials to be taken and rules governing labor discipline. Among the cadres, we have, according to the demands made by the responsibilities attached to each post, laid down detailed rules and regulations governing the actions of individuals, including basic responsibilities, assessment standards and work processes, thus ensuring that, within the enterprise, there will be fixed demands made on every work post. We have also sought to combine strict examination with rewards, and have adopted a method comprising standards, assessments and rewards or punishments. We have taken the first step in setting up a data management system. In using quotas, measurements, original records and statistics, we let the data speak for themselves so as to arrive at a more accurate estimate of the production efficiency of the factories, mines, workships, teams and groups, down to each post. We have devoted much effort to completing measuring facilities. The whole company has already installed 9,685 measuring instruments of various kinds and 24 large-scale weighing apparatus. Among the factories, they have set up measuring nets for molten iron, steel ingots, billets, and steel products. We have completed the preliminary establishment of driving force measuring nets for electricity, steam, and gas. The installation rate of meters reached: 72 percent for electricity, 76 percent for steam, 96.2 percent for furnace gas, and 74 percent for blast furnace gas respectively. The weighing-in rate for goods and materials arriving at the factories increased to 82 percent from the mere 4 percent of the past few years. All products leaving the factories are weighed and checked, so as to ensure that the various production management activities of the enterprise will, through an accurate and sensitive information system, be reflected in the data.

Last year, with the basics of the system of responsibility and the various specialized management systems at our disposal, we forged ahead with the full implementation of the rules and regulations. We convened a special staff and workers congress so as to be able to make certain decisions. First, we requested leading administrative cadres at every level to treat the implementation of the rules and regulations as their prime duty. From the company manager, directors of factories and mines, and workshop directors right down to the directors of teams and groups, everyone is, according to the principles of the regional responsibility system, responsible for the formulation, implementation, examination and management work within their sphere of control. Every specialist management department must divide up work according to the expertise required and be responsible for the implementation, examination, analysis and management of the rules and regulations within their sphere of control. Second, we have implemented the "twelve articles" stipulation under which people are closely scrutinized, rewarded and punished in an impartial fashion, and subjected to strict discipline. It is clearly stipulated that cadres and workers who violate the system and break the rules will, regardless of whether an error was committed, an accident occurred or a loss sustained, be registered and reported to their superiors, and the incident will be notched up against them. Further, they will be disqualified from claiming awards that month. By means of this effective series of controls, we have further stabilized production and effected the overall strengthening of the administration and management of production technology within the enterprise.

/2. To use the expanded powers to carry out internal readjustment within the enterprise./

After the expansion of power, the 50 percent of the depreciation fees retained by the enterprise in the past rose to 80 percent, and then to 100 percent. The depreciation rate also rose from 3.3 percent in the past to 3.8 percent and then 4.3 percent. In 1979 and 1980, the depreciation fees left for the enterprise to distribute rose by 31.44 million yuan. In these 2 years, we further obtained a production development fund worth 21.49 million yuan. Taking these two sums with the major overhaul fund, the enterprise has a stable source of funds every year. Thus the enterprise has the preconditions for proceeding from reality, making long-term plans and early preparations, and concentrating its financial resources on the implementation of measures which cost little, yet produce the desired effect within a short space of time, so as to carry out a rational technological restructuring of the old factories.

For example, our company's No 2 sintering workshop used to produce hot ore. It was technologically backward and there was serious pollution. After adopting technological restructuring, we changed over to cool ore, and vast amounts of unmanageable high temperature smog can now be eliminated during the technological process. This is the best means of controlling the pollution caused by sintering. We can, at the same time, after changing over to cool ore technology, use this in conjunction with the new No 2 blast furnace which has a complete system of conveyor belts and burns top quality ore, so that this blast furnace will be provided with high quality raw materials. Otherwise, when the new No 2 furnace starts burning, it will have to consume vast amounts of imported ore, and we will have to spend an extra 30-odd million yuan. In the second half of 1979, we amassed 8.22 million yuan worth of funds and, mustering our construction strength, managed to carry out cool ore restructuring within the space of just over 2 months and before the new No 2 furnace came into operation, thus guaranteeing the production demands of the new No 2 furnace. At the same time we have solved the problem of how to control the smog and have cleared up the pollution.

In the past 2 years, we have also made use of 21.87 percent of our own funds to implement some key energy saving measures. In 1979, we first carried out the technological restructuring of three industrial boilers installed in the 1950's in the four boiler rooms. They were all converted from coal to blast furnace gas, and they came into operation the very year we went to work on them. Last year we started using again the 1.4 cubic meters of blast furnace gas that had been abandoned in the past, which was equivalent to saving 40,000 tons of standard gas, bringing in an income of 1.65 million yuan. In 1980, we carried out the restructuring of soaking pits in the first stage steel rolling mill. They were converted from burning heavy oil to burning both heavy oil and blast furnace gas, thus greatly reducing the consumption of heavy oil. In 1 year, 12,900 tons of heavy oil was saved, a saving of 0.75 million-odd yuan. Because certain energy saving measures have produced the desired results within short space of time since coming into operation at certain key links in the production chain, the level of energy consumption in the past 2 years has continuously fallen.

Since the setting up of trial points, we have still been using part of the enterprises own funds and actively readjusting the proportionate relations between the "bones" and the "flesh." We have been actively solving the inherited problem of pollution caused by the production process, and have invested a total of 19.9 million yuan out of our funds, 3.71 million of which we raised by ourselves. Now, the Shoudu Iron and Steel Company basically solved the problem of harnessing water. The quality of drinking water has reached national standards and the rate of circulation and utilization of water has already topped 87 percent. There has also been a marked improvement as far as smog pollution is concerned. We have already eliminated those "black dragons" from the sky. The pass rate of the 35 main smog-emitting chimneys in the factory area has reached 68 percent. In the past 2 years, we have also devoted major efforts to reorganizing the face of the factory and to beautifying the environment. In 1979 and 1980, using 16.43 million yuan of funds we had raised ourselves and some capital construction funds, we constructed 174,000 square meters of housing for our staff and workers, thus alleviating to a certain extent the housing shortage they are faced with.

With the expansion of enterprise autonomy, the enterprise now has some economic preconditions for self-development and self-stimulated growth, thus altering the past situation where it had to rely on annual investment and projects for its livelihood and enabling the enterprise to have, after completing the task of turning over income to the state treasury, the preconditions for carrying out modernization and restructuring according to its own situation, its own capacity, and in an economically rational manner. Viewed in the light, it seems that there is more money left in the hands of the enterprise, but this money is different from money invested by the state. In spending "money earned by blood, sweat and tears," there will be careful calculation and strict budgeting. Some important matters concerning technological measures and collective welfare still need to be entrusted to specialized personnel and sumbitted to a staff and workers' congress for discussion. Practice has shown, that under the guidance of macroeconomic planning, when some financial powers are reserved for the enterprise and the enterprise is truly livened up, massive savings can be achieved, which is favorable to readjustment.

/3. To carry out political and ideological education for the staff and workers and to correctly handle the relationship among the three parties./

The reform carried out by the enterprise has basically unified the interests of the state, the enterprise and the individual. So that the staff and workers can see the relationship among the three parties in its correct perspective, we have, in our propaganda and education, adhered to the following principles: that life can only be improved by developing production; that we must continue to foster the spirit of struggling arduously and of hard work and thrift if we are to build the four modernizations; that in handing out rewards, we must bear the cardinal principles in mind, take the overall situation into account and adhere to state policies. Because we have strengthened ideological and political work, we have in the process brought into play everyone's initiative for developing production and increasing profits, thus increasing year by year the results trial-point expansion of power.

The correct handling of the relationship among the three parties mainly involves doing a good job of distribution according to work. After the expansion of power, bonuses were linked to profits. The enterprise could determine for itself the form of the reward. Following the increase in economic effectiveness within the enterprise, although the reward fund has increased in size, we have, in line with state policies, strictly controlled the level of rewards and have not handed out rewards at random. As far as the distribution of bonuses goes, we have adhered to the principle of distribution according to work and have not been guilty of egalitarianism. We have set up an overall championship prize for the few important production factories and mines which have, in their efforts to reach greater heights and standards, achieved results in iron and steelmaking. The level of rewards has thus been raised somewhat. That of some auxiliary departments is somewhat lower. Even units whose standard of rewards is higher find it hard to obtain the overall prize, since they are subjected to harsh tests. After the factories and mines have received their bonuses, they must still be calculated in accordance with the assessment standards laid down by the responsibility system, and implement the rewards according to the workpoints recorded in the workshops, teams, groups and posts, and have thus smashed the egalitarianism of eating out of a "big pot." Due to our strict control over the level of rewards, the enterprise's reward fund has not been exhausted in these 2 years. There has been a surplus every year which the enterprise can use to make up for future deficiencies. Since the implementation of trial points 2 years ago, production at the Shoudu Iron and Steel Company has developed more rapidly and profits have increased somewhat, but the level of rewards among the staff and workers has not been high.

(3)

The Shoudu Iron and Steel Company has fully implemented the policy of readjustment, carried out positive readjustment and steady reform, and has obtained definite results. However, looking at developments in recent years, the Shoudu Iron and Steel Company is faced with a tendency for the enterprise's development funds to continuously fall. In the past 3 years, the enterprise's profits have grown year by year, and state revenue has increased year by year, but the enterprise's income has neverhteless been gradually whittled down. As far as total accumulation of the enterprise is concerned, the ratio of actual state revenue (including industrial and commercial tax, after subtracting basic construction investment and the special fund allocated to the enterprise) to actual income of the enterprise (including basic construction investment and the special fund) was roughly 3:7 for 1978, 5:5 for 1979, and 7:3 for 1980. If we proceed according to the current "change from profit to tax," the ratio will be 9:1 for 1981. Thus, with the enterprise gradually increasing profits, the annual drop in the amount and proportion of actual income and is not conducive to the enterprise increasing income by tapping potential, and to it restructuring and developing itself by relying on its own strength.

As a trial-point enterprise which "substitutes tax for profit, keeps independent accounts and is responsible for its own profits and losses," the Shoudu Iron and Steel Company today no longer receives state investment or special funds. What power can the enterprise rely on to maintain simple reproduction, in particular, for making up for investment in the factories and mines, speeding up pollution control and gradually solving the various problems of the staff and workers, like their housing problem? Moreover, from now on, the scale of the Shoudu Iron and Steel Company will not be expanded further, and during the period of readjustment, the iron and steel industry must cut down slightly on production, keep production targets down and reduce the energy supply, all of which will affect the profits of the enterprise. What solution is there for the enterprise? We are of the opinion that the only solution lies in readjustment and reform. If we are to further implement the policy of readjustment, we must, with the proviso that there will be no further expansion in the scale of the enterprise, persist in the inner readjustment of the enterprise and pursue a new path which will save energy, control pollution, improve quality, expand the variety of products, carry out the intensive processing of products, develop the production of consumer goods, improve administration and management and raise economic gains. If we are to successfully pursue this path, we must give impetus to reform work and, under the guidance of macroeconomic planning, further liven up microeconomics.

However, as for present reforms, for various reasons, trial-point work is in a state of stagnation, and recently there have already been signs of retrogression. A problem which has suddenly appeared in the wake of "changing from profit to tax," is of how to determine regulation of the tax rate. Last year, the regulation of the tax rate for the Shoudu Iron and Steel Company was 13.2 percent. On top of that, the enterprise has to pay income tax, local construction tax, fixed assets appropriation fees and liquid assets appropriation fees. After that, the enterprise is not left with much. Under the present "change from profit to tax," the enterprise keeps a mere 13 yuan for every 100 yuan of profit. Thus the enterprise is receiving too little. Within iron and steel integrated enterprises, metallurgical mines have the characteristic of being able to take over. The Qianan mine of the Shoudu Iron and Steel Company has been in operation for 20 years, during which period the problem of ageing has grown increasingly prominent. If the mine is to maintain normal production and to adapt itself to the iron and steel production capacity, investments need to be replenished every year. Last year, document 226 of the State Council clearly stipulated that we must, "in line with the principle of maintaining mines with mines," "leave most or even all of" the profits from the mines "in the hands of the enterprises, thus ensuring that the mines have a steady source of funds." But for the moment, the stipulation of document 226 concerning mines has not been put into effect at all. The enterprises can neither get their hands on the money invested by the state in the mines nor can they arise these funds from their profits. In the long run, the mines will find it hard even to maintain simple reproduction and the situation will definitely create new, even more serious disproportion. Should such disproportion occur in the mines, any redirection back to the state would cause too great a loss. Let us take as another example the rather large amount of debts owed by the Shoudu Iron and Steel Company in respect of environmental pollution, as certain inherited problems have not been solved. Therefore, we should consider these factors when it comes to distribution profits.

In accordance with the policy laid down by the Central Committee, we must proceed with reform that is favorable to readjustment and to livening up the economy. We should, as far as the present reform is concerned, integrate the blocked up with the cleared, and increases in income with decreases in expenditure. We should also ensure that enterprises can first guarantee a source of income for the state and then that greater material wealth is created for the enterprises so that they can furnish definite economic preconditions. We welcome the type of reform introduced in the old enterprise of the Shoudu Iron and Steel Company, which "substitutes tax for profit, practices independent accounting responsibility for its own profits and losses," as the fixed tax rate should not cut too deeply into the enterprises. We are still considering the adoption of another method. With the proviso that the income of the state and localities increases year by year, we can delineate which method of distribution to adopt between the state and the enterprise. Once this line has been established, it will not be changed for several years. Thus the economic responsibility of the enterprise to the state will be rigidly defined, while the enterprise will be livened up. Proceeding from the actual conditions prevailing in the Shoudu Iron and Steel Company, our specific opinion is: We should fix the tax rate in the ratio of 70 percent of total accumulation to the state and 30 percent to the enterprise, thus conforming to the 1980 level for the distribution of profits. In this way, we will first be guaranteeing the steady growth of state finance and also ensuring that the enterprise has a definite source of funds on which to plan further. Thus we will arouse more fully the initiative of the broad masses of staff and workers to devote themselves to the four modernizations and will, abiding by the policies and decrees of the party and the state, effect the modernization and restructuring of the enterprises step by step in a planned way.

INDUSTRY

INCREASED PRODUCTION OF CONSUMER GOODS CITED

Jinan DAZHONG RIBAO in Chinese 21 Jul 81 p 1

[Article by Jian Zelin [5592 0463 2651]: "Province's Light Industry Strives to Increase Output of Consumer Goods for Daily Use; During First Half of Year 55.5 Percent of Plan Fulfilled; Great Increases in 15 Major Products; Successful Development of 51 New Products"]

[Text] The province's light industry has continued to develop in the midst of further readjustment of the national economy, and tremendous growth has taken place in consumer goods urgently needed by the people in their daily lives. Industrial output value completed during the first half of this year showed an 11 percent increase over the same period last year, and 55.5 percent of this year's plan has already been fulfilled. For the first half of the year, output of 11 of 20 major products achieved "double more than half," and output of 15 products increased over the same period last year. This included a new increase of 150,000 bicycles, 100,000 sewing machines, 350,000 wristwatches, 100,000 clocks, 59,000 cases of cigarettes, 880,000 tons of crude salt, and 5,700 tons of alcoholic beverages. Consumer goods such as beet sugar, dry cell batteries, and synthetic detergents also showed rather tremendous increases.

Major efforts to increase output of consumer goods for daily life is a major task of the province's light industry during readjustment. In drawing up this year's production, acting in accordance with market requirements and requirements for further readjustment of the national economy, the entire system made its focus the increased output of goods urgently needed by the masses, or goods in short supply, such as bicycles, sewing machines, wristwatches, clocks, cigarettes, alcoholic beverages, high quality paper, beet sugar, canned goods, porcelain and pottery, common plate glass, and alcohol to rouse development of light industry overall. In order to increase output of these 12 goods with all possible speed, they tapped unused potential for production within enterprises, while at the same time using mechanized industrial techniques in conjunction with equipment advantages, making a major effort in cooperative and unified production. As a result of several years of battle, the industries in the province that make the "three major items [bicycles, sewing machines, and wristwatches] have increased their production capacity tremendously; however, development of some components has not been rapid to the impairment of the development of production. In the course of readjustment and reorganization this year, they selected some plants in which production conditions are good and technology similar to arrange for components in short supply. At the same time, they have entered into cooperation with military industries to use unified methods to expand production. In this way, the free wheels, sprockets, and saddle seats that have always been in short supply, as well as some sewing machine components have increased tremendously over former years to assure the needs of major machinery plants. In expanding production of the "three major items," the light industry system gave attention to seeking development through internal readjustment, making equitable divisions of labor among enterprises producing bicycles and wristwatches, assigning different kinds of items and specification on the basis of conditions and technical levels of individual enterprises, gradually developing in the direction of specialization, strictly checking on demands from each jurisdiction for new items, and not going ahead with anything that was not absolutely necessary, so as to avoid producing blindly and duplicating construction.

In the process of developing production of consumer goods for daily use, Shandong Province's light industry actively improved upon the make-up of goods, increasing production of goods that enjoyed good markets. Along with the steady increase in people's standard of living, people in both the cities and the countryside have had rising expectations of light industry products. In order to meet these expectations, the entire system initiated improvements in the make-up of products, steadily increasing saleable goods that meet people's needs. The cigarette industry used tobacco leaf grown within the province to develop production of cigarettes containing high and medium grade tobacco, at the same time giving close attention to aluminum foil and cigarette filters, greatly increasing the proportion of quality cigarettes. During the first half of this year alone, output of cigarettes of second grade and above, and of filter cigarettes amounted to 132,000 cases, almost twofold the number for the same period last year. The ceramics industry resorted to a series of measures including decrease in the number of small items, raising the number of large items, holding down the number of individual items in favor of producing sets of items to bring about a tremendous increase in production of ceramic sets, both satisfying export and domestic market needs, and increasing the earnings of enterprises.

The widening of production avenues and major efforts in diversification have been a major measure in the light industry sector of Shandong Province's vigorous efforts to develop consumer goods needed for daily use. The alcoholic beverage industry made full use of the province's resources to increase production of fruit wines, alcoholic drinks mixed with fruit juices, and light sparkling wines. The light industry bureau of Yantai Prefecture alone researched and developed more than 20 varieties of fruit wines and light sparkling wines, producing 10,400 tons of them during the first half of the year both making full use of local resources and allaying the shortage of beer, while at the same time adding to supplies for the summer market. Numerous enterprises also combined their individual production characteristics in major diversification endeavors. The Yidou Match Plant used inferior materials not suitable for making matches to manufacture fiber board. The Rongcheng County Sugar Plant took advantage of the slack season in sugarcane crushing to produce various kinds of sweets and breads, gaining very good economic results therefrom. With the needs of city and countryside markets in mind, a number of light industry enterprises researched and developed new products. During the first half of the year alone, they successfully test manufactured 51 new products including China cypress paper, high quality glossy ganoderma cold cream

[7227 5347 7208], wheat strawboard with one adhesive side, high quality quartz clocks, and dry red grape wine, some of which has already been marketed.

In the development of consumer goods, the light industry system of the province has diligently implemented economic policies and vigorously pushed a system of economic responsibility. The textile bureaus in Qingdao and Jinan instituted throughout all enterprises a system of work quotas whereby the greater the excess profits, the more retained. Each enterprise also contracted output targets with workshops, factory teams and groups, and individuals so that their responsibilities would be clear and their goals well defined. This greatly aroused the enthusiasm of enterprises and of their staffs and employees to strive to increase output and increase earnings, this year's economic results consequently showing clear increases. During the first half of this year, light industry throughout the province realized profits and revenues 8.3 percent greater than for the same period last year.

BRIEFS

HEILONGJIANG MUNICIPAL INDUSTRY--Industrial production of Jiamusi Municipality, Heilongjiang Province, has increased steadily in the course of readjustment. Following the 7.8 and 12.4 percent increases in the annual output value in the past 2 years, 1981's semiannual output value showed an increase of 10.5 percent over that of 1980. To satisfy market needs, Jiamusi Municipality has reorganized its machinery enterprises since the beginning of this year. Production at those which produce quality products, enjoy brisk sales and serve agriculture and forestry is being maintained and halted or transferred at those which produce unsalable poor-quality products. Enterprises which produce the same products are being merged and those which have surplus production capacity are assigned to produce badly needed products. Machinery enterprises have been reduced from 29 to 23. Thanks to readjustment, the light industry share of output value in the entire industrial sector has increased from 56.6 percent in 1978 to 60 percent. [Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 17 Aug 81]

HENAN INDUSTRY CONFERENCE--The Henan Provincial CCP Committee and government held an urgent meeting of prefectural and municipal leaders and responsible comrades of provincial departments from 17 to 20 August, which demanded that the cadres and workers throughout the province make every effort to fulfill and overfulfill this year's industrial plans and ensure a 5 percent increase in output value compared with last year. In accordance with the instructions of the Central Committee and State Council, the meeting held warm discussions in connection with the actual situation in the province, and called for all-out efforts in the last 4 months of the year in order to fulfill the plans. The province should do a good job in straightening out the enterprises and implementing economic responsibility systems. [Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 22 Aug 81]

GUANGDONG ECONOMIC WORK--Guangdong Province achieved noticeable success in increasing industrial output and revenue during the first half of this year. Compared with the same period last year, the total value of the province's industrial output and revenue during the first 6 months increased by 11 and 11.89 percent respectively while energy consumption was lowered by 3 percent. During the first 7 months, the gross value of light industrial and textile production in the province increased by 16 percent and the gross value of the province's heavy industrial production rose by 2 percent over the same period last year. According to Li Jianan, vice governor of Guangdong, such achievements are the result of measures carried out in most of Guangdong's state-owned enterprises to arouse the workers' production enthusiasm. [OW270557 Beijing Domestic Service in Mandarin 1200 GMT 24 Aug 81]

ANHUI TEXTILE CONFERENCE--The Anhui provincial conference on textile industry was recently held in Hefei. It calls on all textile mills in the province to work hard to fulfill their goals of increasing their production by 15 percent and their profit by 12 percent in 1981 over the figures in 1980. [OW240453 Hefei Anhui Provincial Service in Mandarin 1100 GMT 24 Aug 81]

GUANGDONG METALLURGICAL INDUSTRY'S ACHIEVEMENTS--In studying the documents of the 6th Plenary Session of the 11th CCP Central Committee and Comrade Hu Yaobang's important speech, Guangdong Province's metallurgical industry party group has summed up their achievements scored in implementing the readjustment principles. Reviewing the situations before and after the Third Plenary Session, the party group of the province's metallurgical industry held that the current situation is very promising. The industrial structure has been readjusted and consumption of fuel lowered every year. Up to now, 49 small-scale iron and steel plants have been suspended, saving the fuel and labor for the backbone plants and the light and textile industries. Large and comprehensive plants have also been readjusted and amalgamated to save fuel and maintain a more rational structure. In addition, the orientation of production has been changed and more marketable products have been produced. Management of business has also been improved which in turn has promoted business and increased production. Another achievement is that the production responsibility systems have been pushed forward and subsequently improved the economic effect. In 1980, the total amount of profits submitted by the province's metallurgical industry to the state amounted to 106.28 million yuan, showing an increase of 119.8 percent over 1978. [HK210829 Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 14 Aug 81]

JILIN CONSUMER GOODS--People's demands for expensive consumer goods are increasing, according to a recent investigation by the Provincial Planning Commission and Jilin University on 32 consumer goods in Changchun, Siping and Yanji Municipalities, Yushu Town and Huaide, Nongan, Hailong, Shulan and Tongyu Counties. In 1980 the monthly per-capita income of the 2,671 families in the three municipalities and the town was 28.7 yuan, 8.7 percent higher than in 1979. The annual per-capita income of the 4,334 families in the five counties was 208.5 yuan, 13.2 percent higher than in 1979. Of the over 7,000 families, every 1,000 persons are waiting to purchase 29 bicycles and 17 wristwatches; every 100 households are waiting to purchase 9 sewing machines, 4 radios and 3 television sets. 'JINGJI GUANLI' ON CONSTRUCTION INDUSTRY

KH010824 Beijing JINGJI GUANLI [ECONOMIC MANAGEMENT] in Chinese No 7, 15 Jul 81
p 23-24

[Article by Xue Baoding [6585 5508 7844] and Lin Senmu [2651 2773 2606] of the Economics Research Institute of the State Construction Commission: "Pay Attention To and Develop the Construction Industry"--slantlines denote boldface]

[Text] The construction industry is one of the three important mainstays of the national economy and is regarded as a basic material production sector in an economically developed country. However, the construction industry remains quite backward in our country and, actually was not considered as a basic material production sector for a long period of time. In national economic plans, we can find production targets ranging from how many million tons of iron and steel being produced a year to how many watches and bicycles a year; but nothing is mentioned about how many houses are built a year. In contrast to Western capitalist countries and the Soviet Union and some East European countries which always included the number of workers' residences built each year as a useful index in appraising improvements in their people's livelihood. The governments of these countries have adopted many policies and measures to boost their construction industries. By developing the construction industry, they have pushed ahead the development of the iron and steel industry, the plastic's industry, the machine-building industry, the household electric appliance industry and so on, thus causing their national economies to prosper.

For a long period of time, our construction industry has not received due attention. Many policies and measures which we have adopted did not foster the construction industry but weakened and restrained its development. (1) Concerning the profit policy, every trade in our country enjoys a fair profit margin. For example, it is 70 percent or higher for the petroleum industry; 60 percent for the electrical-generating industry; 20 percent or higher for the machine-building industry; and 5 percent even for the armament industry. However, the construction industry has never enjoyed a reasonable profit. The legal profit for the construction industry was 2.5 percent before 1958, which was actually much lower than that for other industrial sectors. Even this meager profit was taken away in 1959, and it was not resumed until last year as a result of the urging from different quarters. This practice has long been keeping the construction industry in a situation of relying on the supply system and eating in the same canteen with everyone else, and hence adversely affecting the enthusiasm of enterprises in developing production and improving business administration.

//2) The material supply system is irrational too.// As everybody knows, the task of the construction industry is to build houses. However, in our country, construction materials are not distributed to construction units but to different project units according to the allocation of capital construction funds. Then the construction units in turn request materials from the project units concerned. This procedure which deliberately separates laborers from objects of labor creates the segmentation of the productive forces of enterprises. At the same time, such a provision system brings about formidable wastes. For one thing, it has greatly lowered the completion rate. According to the statistics by the general bureau of construction projects, in the period of "the first 5-year plan" when the system of contracting for jobs and materials was in effect, the completion rate for ordinary civil construction reached 61 percent, in contrast to the 46.5 percent of last year. In other words, if we reached the same level as in the period of "the first 5-year plan," we would have completed a residential area of 15 million square meters more in 1980. Another thing has been the poor utilization of manpower. There are 60,000-odd construction projects of various kinds under construction at present. Every construction project needs a number of persons to arrange materials and equipment. The number ranges a minimum of 3 to 500 at a typical project. This amounts to 350,000 for all the projects throughout the country. The salaries and traveling expenses for these persons amount to 300 million yuan or more a year. As estimated, the expenses for this purpose have amounted to 36 billion yuan at least since this system of providing materials to project units has been enforced. Moreover, waste in material resources needs to be considered too. To distribute materials to each unit is bound to increase circulation links and bring about duplication in organization and warehousing. From manufacturing to construction sites, large amounts of construction materials have to go through 3 separate components--the material department, the project unit and the unit in charge of construction--as well as, more than 10 links. The cost alone for building provisional warehouses amounts to 200 to 300 million yuan a year. Finally, the overstocking and waste due to nonconformity in type and quality of purchased materials are also tremendous. In our estimation, the expenses our country pays each year for the last two mentioned causes amount to 500 million yuan, equivalent to the expenses for constructing a housing area of 4 to 5 million square meters. Nevertheless, people have scarcely paid attention to this problem and little has been done to change this system which hinders any improvements in the economic effect.

The causes for such a situation are varied. The most direct one lies in the desire to expand the scale of capital construction. Over many years, the "speeding up theory" has been the guiding thought for economic work in our country. And the scale of construction has been blindly expanded under the influence of this theory. The overexpansion of the scale of capital construction which has gone beyond the limits of financial and material resources that the country could afford have resulted in shortages in capital and in materials. In order to remedy this situation, the construction industry has been restrained from developing; measures were taken to cut down or even eliminate the construction industry's profit while the people's desire for more housing was ignored. Construction materials have been distributed to project units while raw materials, fuel, other energy resources and so on which had originally been allocated for production, maintenance and renewal uses have been diverted to promote capital construction in the name of giving full play to their "initiative." This actually a short-sighted policy, a method of killing the goose that lays the golden eggs. It has not only hampered the development of the construction industry but also that of industry, communications and transportation, and so forth; to the last analysis, it has been an obstacle to the development of our country's socialist construction.

The four modernizations can hardly be realized without a developed construction industry. Therefore, we must pay attention to developing the construction industry and make it suit the needs of the four modernization construction.

What is the aim of promoting the construction industry? What steps and measures should be taken to fulfill this aim? We still cannot put forth a comparatively complete proposal at present because we have yet to make a comprehensive and systematic survey. Generally, our tentative idea is to transform the construction industry into an independent and substantial material producing sector, readjust its internal structure, strengthen the activities of enterprises, promote the production of construction commodities, improve the comprehensive economic effect and eventually turn it into a firm mainstay of the national economy. Based on this tentative idea, we reckon, the following problems should emphatically be solved in the period of the Sixth Five-Year Plan.

(1) //To place the production activities of the construction industry into the plan of the national economy,// in which the total output value of construction and installation, the total production value of construction products and the housing construction volume (in square meters or apartment units) is included. On the other hand, in consideration of the characteristics of large volume of construction products and a long construction cycle, we must move up the development of proposals for each year and approve and release the capital construction plan for the following year by the end of September. The construction units must be included in the annual plans, and no gap must be left in the chain of capital allocation and materials distribution so that the "trilateral state" can be eliminated. Moreover, we have to ponder how to improve planning, the administration of funds, and so on. The old way of practice--to allocate funds at the beginning of a year and terminate all accounts at the end of the year--should be changed, and a developmental planning system should be experimentally enforced step by step.

(2) //Reform the way of material distribution.// We must establish a relation of material balance of the construction industry to the national economy. Instead of distributing construction materials by every 10,000 yuan of capital construction investment and construction project, we can directly distribute the materials and equipment needed to construction units according to the principle of unification of manpower, material and financial resources, and allow the construction units the right to contract for both job and materials and assume the full responsibility for the completion time and quality of the contracted projects.

(3) //Improve the forms of investment and promote the "unified management" of housing construction. The following form is worth considering; in cities and areas where tasks of housing construction are concentrated, take over land in a unified way in the name of the state according to scientific, economic planning and construction planning; assign housing construction tasks directly to construction enterprises and correspondingly distribute the necessary materials and circulating funds to them; let the construction departments take over the unified design and construction, carry out "unified management," and sell the completed housing by apartment

units at fixed prices. As for the basic facilities such as water supply, electricity, gas, telephone and so on, we can organize management companies which can oversee them in a unified way. The contract system of taking complete responsibility must be widely adopted for all those sites where houses, public buildings, industrial buildings and so forth cannot be built in large numbers.

(4) //Expand the decisionmaking power of enterprises and enable them to play a dynamic role in promoting production and management.// All construction enterprises must carry out strict accounting and separately calculate profits and losses. For those construction enterprises newly founded by the authorization of the department in charge, the government should set up the fixed assets, circulating funds, revolving materials and welfare facilities which are necessary, in the same way as for industrial enterprises.

(5) //Readjust the price policy and reform the price structure.// Apart from production costs, the price of construction products should also include reasonable profits and taxes. The profit rate should in principle be no lower than the average level of industrial enterprises, so that construction enterprises can operate under normal production conditions and rational management, and enjoy a little profit after taking care of expenses with revenues. For housing projects, the currently used tedious budget system should be replaced by another system of setting price by square meter, and enterprises should be allowed to enjoy the power to set price within flexible limits. The method of encouraging construction enterprises to compete with each other by submitting bids should also be further studied.

(6) //Reform the multifacet administration of the construction industry.// At present, there are 7 million construction teams throughout the country subordinate to 20-odd departments, all of which are independent of each other. This is really a construction administration system of multidepartments and multilevels and should be reformed. The principles for reform must be worked out so as to break up the situation whereby departments are separated and areas are divided up to end independent departmental operations, promote the contract system and organize integration between enterprises. As a first step all planning, design and construction enterprises, in particular those teams which report directly to departments, should try out a system combined accounting with project units in the next 2 years. They should adopt a contract system which encompasses all aspects, do their own accounting and operate independently to minimize their dependency on departmental supervision. Those which do not get enough jobs must readjust their production orientation and strengthen their adaptability. On such a basis, develop ways to further liberate construction enterprises from departmental and regional confinement with the support of administrative authorities, to promote integration and establish trade organizations of the construction industry.

BRIEFS

GUANGXI RURAL HOUSEBUILDING--This year, the State Capital Construction Commission and Guangxi Autonomous Region have supplied 5,000 tons of rolled steel, 22,000 tons of cement, some 52,000 cases of glass and a large quantity of timber to rural areas to build houses. Meanwhile, the Regional People's Government has also appropriated a large amount of funds for rural house building. To do well in rural house building, the Regional Capital Construction Committee and the Regional Construction Material Bureau held a conference at the end of July on the production and supply of construction materials for rural house building. The conference decided to manufacture a large quantity of attractive, practical, good quality and cheap cement parts and to supply them to peasants. CANCELED, SUSPENDED PROJECTS--Jinan, 23 Aug (XINHUA)--The national conference on problems arising from canceled or suspended projects was held in Jinan Municipality of Shandong Province from 16 to 23 August. The conference called by the State Capital Construction Commission and the State Council's office in charge of clearing up projects under construction was attended by responsible comrades from capital construction commissions of various provinces, municipalities, autonomous regions and from the departments concerned. The conference studied the relevant instructions issued by the State Council and stressed that all localities, departments and units must do their best to provide good care, maintenance, and use of the equipment of those projects that have been canceled or suspended. The conference also stressed that the operational responsibility system in operation must be set up at various units. [OW271047 Beijing XINHUA Domestic Service in Chinese 1640 GMT 23 Aug 81]

BRIEFS

GUANGDONG SMUGGLING ACTIVITIES--The Guangdong Provincial People's Government conference on striking blows at smuggling activities, which concluded on 10 August, formulated a regulation strictly prohibiting all enterprises, organs, organizations, PLA units, party members, cadres, armymen, staff and workers from buying smuggled goods, from smuggling and from selling smuggled goods. All smuggled goods shall be confiscated and offenders shall be punished at the place where they commit crimes or at their native places. The conference demanded that leaders at all levels exercise leadership over this antismuggling struggle and take the lead in opposing smuggling activities. INCREASED EFFICIENCY FROM INDUSTRIAL SYSTEM OF RESPONSIBILITY REPORTED

Nanjing XINHUA RIBAO in Chinese 18 Jul 81 p 1

[Article by Chen De [7115 1795] and Wang Liangfu [3769 5328 1381]: "Application to Industry of Agricultural System of Responsibility in Which Calculation of Remuneration Is Linked to Output; Twenty-two Collective Enterprises in Guwang District Try Out Piece Rate Wage Methods to Take on a New Look"]

[Text] Guwang District in Xuzhou City has applied to industry the agricultural system of responsibility whereby calculation of remuneration is linked to output, instituting trial piece rate wage methods in 22 collective enterprises to win fine economic benefits.

In accordance with their individual characteristics, each of these 22 enterprises began last year to use seven methods to calculate remuneration, including level by level management, specialized contracting, small collective piece rates, piece rates for production in excess of set quotas, unrestricted piece rates for individuals, minimal salary plus piece rate, and fluctuating wages. These are characterized by: Linking of a system of responsibility for production to the economic well-being of staff and employees in accordance with the principle of "from each according to his ability, to each according to his work." Basic wages are solely for reference in setting unit prices; they do not function to assure a specific amount of distribution; however, basic wages apply for vacations, sick leave or maternity leave. Each enterprise clearly stipulated that increases in wages paid staff and employees could not exceed increases in production or increases in the labor productivity rate, nor could they exceed increases in enterprise profits, and they must take into full account the welfare of the state, the collective, and individuals. Verification of quotas, labor quotas, and pertinent regulations would be stipulated or revised by meetings of staff and worker delegates or through democratic discussion by staff and workers.

Following trial implementation of this new method of calculating remuneration, a new atmosphere such as had not been seen in many a year began to emerge in these enterprises.

Out went the "eating out of a common pot," and the enthusiasm for production of the broad masses of staff and employees was aroused. Formerly in these enterprises, it was a case of "guaranteed harvest no matter drought or flood" in regard to the wages of staff and employees in an egalitarian tendency to get the same wages every month. After institution of the new method of calculating remuneration, whether one worked well or worked poorly, worked much or worked little, worked or did not work, all made a difference, and the zeal of the workers was aroused. At the Guwang Transportation Company, some workers responsible for loading and unloading used to report for their shift only to take off as soon as attendance was checked. When a truck showed up no one was available to load it, and there was no choice but to send temporary workers or peasant workers to do the job. Now they all get to work early and leave late, and actively look for work to do. One person now does the work three used to do, and only one truck is needed to do what it formerly took three trucks to do. The labor productivity rate has vastly increased. After piece rate wages were instituted, some old workers praised the system saying the responsibility was now placed on individuals; they are encouraged to take the lead; their integrity is better, they work with energy; and the enterprise has some prospects. This is the only way to come up to the socialist mark.

Cadre work styles have changed. Now that cadres in these enterprises have fluctuating wages whereby "when the water rises all boats rise," and "when the water falls, all boats fall," how well enterprises are managed is intimately related to the size of the incomes of cadres individually. This has caused cadres and management personnel to go down to the grassroots, to investigate and study, and to verify quotas. It has made cadres study administration and management, to become familiar with operations, and to do a good job of all types of work. All the comrades in charge at the Guwang Transportation Company have changed their old practice of "dawdling" in meetings, and have gone to the front lines to organize production and direct production.

All systems have been perfected. Formerly in many enterprises there were no quotas to verify, no quotas for labor, and no responsibility attached to positions. Management was chaotic. After the new method of calculating remuneration was instituted, every unit acted in accordance with realities to establish and perfect systems of various kinds, which were put into effect from top to bottom and from left to right, giving a new order to production. Because of the former lack of necessary rules and regulations, the Guwang Shoe Plant frequently lacked finished goods or semi-finished goods, and even needles, and spools of thread. Now, for every working procedure and every position a fixed consumption quota has been established; cost accounting has been instituted; and every expenditure relates to individual wages. As a result, the system is formulated by everyone, and the loopholes are closed by everyone; problems that could not be solved for more than 20 years have rapidly found a solution.

Output has risen very rapidly. Because of a lack of quality controls, the glazed tiles produced by the Guwang Ceramic Plant caused losses. After institution of piece rate wages this March, the plant contracted materials consumption, worktime quotas, and quality standards with workshops, and with plant teams and groups. The workers themselves instituted strict quality control over every process, and the finished product rate per million glazed tiles rose from the former 30 percent to 62.7 percent, the income from this item alone increasing by more than 30,000 yuan.

The state gains more; the collective keeps more; and individuals get more. After the Guwang District No 2 Brick and Tile Plant instituted piece rate wages this April, it made profits in the same month of more than 9,000 yuan, of which more than 5,300 yuan was paid the state in revenues, more than 2,700 yuan was retained by the collective, and 880 yuan was shared among workers, each person getting an average of 7.86 yuan. The workers said happily: "Trial piece rate wages benefit the state, the collective, and the individual."

WAGE INCREASES RESULTING FROM DECREASED COSTS, ACCUMULATIONS DISCUSSED

Beijing GONGSHE CAIWU [COMMUNE FINANCIAL AFFAIRS] in Chinese No 7, 6 Jul 81
pp 15-17

[Article by Gong Cai [0361 2088]: "Tremendous Increase in Income Distributions to Rural Commune Members in Shandong Province"]

[Text] As a result of the enduring erroneous influence of the left in the past, development of agriculture in rural Shandong was slow, and the level of collective distributions was very low. Average distribution of earnings per commune member were only 57.60 yuan in 1976, a 5.70 yuan increase in 20 years for an annual per capita average of only 0.28 yuan.

Since the Third Plenary Session of the 11th Party Central Committee, great changes have taken place in the rural villages. In 1980, gross income for agriculture, forestry, animal husbandry, sideline occupations, and fisheries in production brigades the production teams increased by 17.9 percent folloiwng a 14.5 percent increase in 1978 and another increase of 15.6 percent in 1979. Accompanying development of the collective economy has been a tremendous increase in the level of distribution of earnings to commune members. Per capita distributions averaged 58.60 yuan in 1977, 68.40 yuan in 1978, and 81.50 yuan in 1979. Last year, they increased to 105.20 yuan, a 47.60 yuan or 82.6 percent increase over 1976. Even more heartening is the great changes that have taken place in the poverty stricken four prefectures of northwestern Shandong. In these four prefectures, average per capita distributions of income rose from 50.90 yuan in 1979 to 87.40 yuan, a 36.50 yuan increase. In Liaocheng Prefecture, average income rose from 54.80 to 126 yuan, a 71.20 yuan increase. Within a single year, numerous communes and brigades that had long been poverty stricken reversed their situation of "dependence on uniform sales for grain to eat, dependence on loans for production, and dependence on relief for a living." Throughout the province, a whole group of fairly prosperous units has appeared. Counties with average per capita incomes of more than 200 yuan have increased from last year's 4 to 12, and production brigades with average per capita incomes of more than 300 yuan have increased from 47 to 698. These heartening changes are the result of diligent implementation of a series of the party's rural programs and policies, of which, concretely speaking, the following have been the principal ones.

1. A System of Responsibility Has Aroused the Enthusiasm for Production of the Peasants.

Along with the implementation by all levels of the party and government during the past several years of pricing policies and award sales policies in the state procurement of agricultural byproducts, has been a breaking of the fetters of the leftist mentality, respect for the self-determination of production teams, and the promotion of various forms of a system of responbility for production through the adaptation of general methods to local situations. This has effectively triumphed over the egalitarian phenomenon of "a great commotion in doing work," and "leveling out of distributions," has put into practice the socialist principle of distributions in accordance with work, and has aroused the enthusiasm for production of the masses. Already 74.4 percent of the more than 400,000 grassroots accounting units have instituted various forms of a system of responsibility for production, and 23.3 percent of them have instituted a system of responsiblity of fixed work quotas. Only 2.3 percent have not unequivocally set up a system of responsibility. Experience has shown that no matter the form of a system of responsiblity, so long as it takes into account the realities of local units in local areas, it will play a major role in arousing enthusiasm for increased output and savings by the masses. Liaocheng Prefecture, which has always been fairly poor, did an early and a good job of setting up a system of responsiblity for cotton, instituting chiefly uniform administration and linking output to individual workers, thereby winning a bumper harvest. Average per capita distributions to commune members increased over last year by more than 100 percent. Xiajin County in Dezhou Prefecture has always been a very poor county. In 1979, average per capita distributions in the county amounted to only 45.70 yuan. In 1980, more than 90 percent of production teams instituted fixed work quotas on a household basis, and fixed output on a household basis. Earnings distributions tripled to 154 yuan. Fairly prosperous Yantai Prefecture instituted fixed work quotas for teams and for individuals for its open field crops, and in forestry, animal husbandry, sideline occupations, and the fishing industry specialized contracts were instituted with remuneration being calculated on the basis of production. For each piece of farm machinery a system of individual accounting was instituted, and results in increased output and savings are remarkable. Average per capita distributions to commune members rose from 156.00 yuan in 1979 to 191 yuan, income levels becoming the highest in the province.

2. Made the Most of Advantages for Producing Economic Crops Such as Cotton and Peanuts

While maintaining increased grain production as directed by the Provincial CCP Committee, every jurisdiction actively developed a program for economic crops, increasing the cotton and peanut growing are by adapting general methods to local situations. As a result of state increase in the requisition procurement price it would pay for cotton, the widespread publicity given to the grain equivalency of cotton instituted by the Provincial CCP Committee, and policies for award sales of grain for sales of cotton in excess of quotas, calculations by basic accounting units show average per capita sales of ginned cotton amounting to 20 jin, an assured 380 jin of consumption grain, and award sales of 4 jin of grain or 2 jin of chemical fertilizer for every jin of cotton sold the state in excess of quotas. Thus, cotton farmers are assured consumption grain, further arousing the enthusiasm of communes and brigades for growing cotton. The area sown to cotton in the province has increased from 8.14 million mu to 8.36 million mu. In addition, advanced techniques have been spread and "Lumian No 1" superior variety of cotton popularized. This plus favorable weather conditions has suddenly increased total cotton output from the previous year's 3.33 million dan to 10.74 million dan, and total peanust production has increased from 21.202,000 dan to 28.08 million dan

Both per unit yields and total output have reached all-time record high levels. This plus the increased price and the ad valorem price for cotton has meant a net increase of 1.5 billion yuan in earnings from economic crops, even allowing for offsetting reduced income from grain as a result of calamities. This amounts to an average 23.10 yuan per capita throughout the province. In the four northwestern prefectures of Shandong, income from the sales of cotton alone averaged 62 yuan per capita.

3. Full Use of Local Resources; Vigorous Development of Diversification

In 1980, earnings from forestry, animal husbandry, sideline occupations and fisheries throughout the province increased by 330 million yuan over the previous year, and individual earnings averaged 72.20 yuan, 5 yuan more than the previous year. Numerous communes and brigades took the road of one principal industry with all around diversification of agriculture, forestry, animal husbandry, sideline occupations, and fisheries to increase both collective earnings and distribution to commune members. Yantai Prefectures, with its consistently high grain output, vigorously developed diversifications and per capita earnings from forestry, animal husbandry, sideline occupations, and fisheries averaged 170 yuan, a 40 yuan increase over 1979. In more than 90 percent of the counties where per capita distributions averaged more than 200 yuan, and in communes and production brigades where per capita distributions averaged more than 300 yuan, earnings from diversification amounted to more than half of total income. In a relatively large number of such production brigades, 70 to 80 percent of total income derived from diversification in industry and sideline occupations.

4. Improvements in Administration and Management Has Lowered Production Costs

Formerly, as a result of the influence of "leftist" ideology, administration and management was chaotic with production taking no account of costs. There was extravagance and waste as a result of which total expenses occupied an ever increasing proportion of total earnings. In 1971, expenses of various kinds in basic accounting units in the province amounted to 32.5 percent of total earnings. In 1977, they climbed to 43 percent. Since 1978, with improvement in administration and management and emphasis on economic accounting, the ratio of expenses has steadily dropped. In 1979, they amounted to 39.9 percent, and in 1980 they dropped to 36.3 percent. In 1980, 498 million yuan in expenses was saved, equivalent to a 7.6 yuan per capita increase in earnings.

5. Proper Readjustment in the Ratio Between Accumulation and Consumption

Because of the current situation of low levels of agricultural output and the unprosperous life of the majority of commune members, collective withholdings and national revenues are held at around 20 percent of net earnings, 80 percent being required for distribution to commune members. This corrects the former erroneous methods whereby accumulation was emphasized and consumption slighted no matter conditions, which limited distributions to commune members. In 1980, the proportion of net income collectively withheld throughout the province dropped from 21.9 percent of the previous year to 19.7 percent, and the portion distributed to commune members increased from 75.5 percent to 77.5 percent. As a result of readjustment of the proportion between accumulation and consumption, distributions have increased by an average 2.90 yuan per capita.

BRIEFS

LIAONING LABOR REFORM--The Liaoning Provincial Public Security Department convened an experience-exchange meeting on the work of reform-through-labor 31 July - 6 August. The meeting's participants held that our province's reform-through-labor work has scored great achievements with the warm concern and vigorous support of various CCP committees and governments. According to statistics compiled in Dalian and Anshan Municipalities, about 80 percent of ex-convicts do not commit offenses after being released. The meeting pointed out: While conducting reform-through-labor work, it is necessary to uphold the principle of "educating and persuading first and reforming through labor afterwards." JILIN RAIL TRANSPORT SEMINAR--The Transportation Economic Committee of the Chinese Railway Association and the Jilin, Liaoning and Heilongjiang branches of the Chinese Railway Association held a seminar in Jilin on 5 August on quality control of railway transport. Attending the meeting were representatives of bureaus concerned under the Ministry of Railways, the Chinese Railway Association, China's 20 railway bureaus and various provincial, municipal and autonomous regional railway associations. About 30 theses were submitted to the meeting. [SK091218 Changchun Jilin Provincial Service in Mandarin 2200 GMT 7 Aug 81]

GUANGDONG'S GUANGZHOU-ZHUHAI ROAD--In order to improve the road conditions for traffic and transport between Guangzhou and Macao, the Guangdong Provincial People's Government has decided to completely rebuild the Guangzhou-Zhuhai Road. The first phase of reconstruction work will be done entirely with foreign capital. The project reconstruction command has now been established and has begun to make preparations before reconstruction. To meet the requirements of the development of our province's industrial and agricultural production and foreign trade, the Provincial People's Government has decided to completely rebuild this road in 3 years. According to statistics, after reconstruction, the Guangzhou-Zhuhai Road will be shortened from 137.6 km to 119 km and it will take some 2 hours to go from Baihedong in Guangzhou to Gongbei in Zhuhai by car instead of 6 hours. MECHANICAL, ELECTRICAL INDUSTRIES TRY REORGANIZATION, INTEGRATION

HK200949 Beijing JINGJI GUANLI [ECONOMIC MANAGEMENT] in Chinese No 6, 15 Jun 81 pp 51-54

[Article by Shashi Municipal Industry Bureau, Hubei Province: "Mechanical and Electrical Industry Struggles for Survival and Development Through Reorganization and Integration"--note passages within slantlines denote boldface type]

[Text] The Shashi municipal mechanical and electrical system is an industrial group dealing mainly with machinery. The whole system is composed of 29 factories, 24 of which are machine building factories. Among their chief products are radial drilling machines, grinding machines, cylinder boring machines, series 135 diesel engines, low pressure valves, multiple speed dynamos, single-phase electric meters, super strainers, electrical accessories for machine tools, standard parts, bearings, and so on.

In the past 2 years, the machine building business of our system has encountered great difficulties in the process of implementing the readjustment guideline of our national economy. For a number of our enterprises, their production plans have decreased in size, their tasks were significantly reduced, and products of many factories were unmarketable. Under such circumstances, instead of getting disheartened and airing grievances and resentment, we made great efforts in adjusting our service orientation and took vigorous steps in directing the enterprises to reorganize themselves and integrate in accordance with the requirements of the readjustment guideline. As a result, the whole system not only overcame the temporary difficulties, but also gained new development on the basis of the old foundation. Total output value of the first municipal machine building bureau increased by 34 percent in 1979 as against 1978, and again increased by 25 percent in comparison with 1979. Profits of the bureau went up by 46 percent in 1979 as compared with 1978, and those for 1980 again outgrew 1979 by 40 percent. In the following, we would like to present three aspects of the problem:

1. The Machine Building Industry Must Change its Service Orientation and Expand its Service Scope During Readjustment.

The readjustment of the machine building industry is a key link of the readjustment of the industrial sector of our country. In 1979, with the principle of combining regulation by planning mechanism and regulation by market mechanism put into effect by the state, the machine building trade nationwide was short of work assignments, and the whole industry was hard pressed. Take our municipality for example, for the beginning of 1980, of the 45 major products of the 29 enterprises, 11 products were encumbered with oversized inventories, and 4 productions were impeded by sluggish markets. Eight enterprises had to reduce their production plan by 12.14 million yuan because of supplies in excess of sales as well as other reasons. Under such circumstances, how the machine building industry should organize its production indeed became a crucial problem.

As we recall, we laid our hands first on the urgent problem of strengthening the competitiveness of our mechanical products, expanding the sales and utility of our products, and getting the factories to work at their "full capacity." We emphasized that we could not just stand by for 3 years during the readjustment. Instead, we should make our plants operate for 3 years, and keep our people in action for 3 years. Our viewpoint was supported against such a background: since the founding of the PRC, our machine building industry has built up a comparatively solid foundation; however, in terms of product range, service orientation, matters of allocation, as well as other aspects, there existed irrational problems. For example, with reference to product range, for a long time in the past, the products of the machine building industry were not regarded as commodities. These products not only required a large amount of state investment and loans, but also lacked economic efficiency and speedy turnover of funds. Besides, they were in no way related to the daily needs of the people in such aspects as clothing, food, dwelling, transportation, and so on. Since economic readjustment is being implemented by our country, requiring the production of consumer goods on a large scale and the transformation of the industrial structure with emphasis on light industry, it is quite evident that the change of the product range of the machine building industry is a matter of strategic alteration rather than a mere change of a certain aspect. Take the service orientation of the machine building industry as another example. In the past, strong emphasis was given to heavy industry, capital construction, and expanded reproduction. Agriculture, light industry, technological, transformation, and giving service to the overseas market were neglected. This gave rise to the inherent evil of wide range fluctuations following the ups and downs of state capital construction investments. As soon as investment in capital construction was reduced, the machine building industry would "operate below capacity," "with nothing to do," and products would be left without a market and financial losses would be inevitable. Since the state is reducing capital construction on a large scale in the process of economic readjustment, it is quite evident that the machine building industry is required to change its service orientation rather radically. The above fully indicates that the readjustment of the machine building industry cannot be completed in 3 years. Even when the period of economic readjustment is completed, the machine building industry will have to continue readjustment according to the requirements of the development of the national economy. This is the only way in which the machine industry will develop and grow without interruption amid readjustment, rendering service to the four modernizations and the livelihood of the people.

On the basis of such a conception, for more than 2 years in the past, we have worked vigorously to change our service orientation, expand incessantly the coverage of our service, and implement resolutely the readjustment of the machine building industry in our municipality. We are mainly carrying out "six transformations."

//1) Change from serving the capital construction sector to serving the light industry market and the daily life of the people.// Due to the reduction of capital construction, some factories that fall short of work assignments have vigorously taken up production of light industrial products and consumer goods for the people's everyday life in accordance with the production facilities of the factory. These products include single phase electric meters, electric fans, transformers, electric current stabilizers, rectifiers, washing machines, safes and other products. Last year, the value of these products accounted for about 20 percent of the total output value of machinery products of our bureau.

//2) Divert services from production of principal products of the machine building trade to the production of spare parts for light industry and textile machinery and to machinery servicing.//

Shashi Municipality is mainly a light and textile industrial center with ample ground for development in the case of the machine-building industry servicing the light and textile industries. In the past year, we have coordinated five factories for the production of dobby machines, down-cutting machines, warping machines, and towel printing machines as well as for the production of equipment, production-line outfits, and molds for casting bicycles and washing machines for the local market. In the meantime, spare parts are produced for light industry products in cooperation with other manufacturers.

//3) Change from manufacturing principal machinery to the production of spare parts and fittings.// In the past, the enterprises paid attention to the manufacturing of principal machinery only, with little arrangements for the production of spare parts and fittings. At present, they are all making vigorous efforts to expand production of parts and fittings. Some enterprises even make special arrangements in accordance with the variety and specifications as required by the customers. Sometimes, at the instruction of customers by mail, the needed parts and fittings are mailed to them.

//4) Shifting from pursuing single-variety and large batch production to multi-variety production.// Starting from 1979, we began coordinating our factories to strenuously develop new products of good marketability in the light of market demand. By 1980, we had an additional 162 products of new varieties and specifications.

//5) Shifting from purely domestic marketing to making strong sale efforts abroad.// A number of factories of our bureau have made great efforts to improve product quality in order to continuously boost the volume of their machinery exports. At present they have made inroads into the international market for the following products: radial drilling machines, valves, cylinder boring machines, standard parts, and so on. In 1980, 248 radial drilling machines were exported covering far-off markets in more than 10 countries, including the United States, West Germany, France, Italy, and so on. Total value of exports for our whole group increased by 74.5 percent in 1980 as against 1979.

//6) Shifting from dependence on state monopolized purchase and marketing to relentlessly grasping market operations.// Comparatively speaking, our bureau has made more early coordination among our factories in seriously analyzing the situation we are faced with in the spirit of the "two regulations" [regulation by planning mechanism and regulation by market mechanism] implemented by the state, and we have shifted from depending on state monopolized purchase and marketing to relentlessly grasping the operation of our own marketing. This has made us realize that vigorous promotion of sales is an important part of the while business of an enterprise as well as an indispensable measure to enliven production. So we have set up strong sales teams in each of our factories. In the case of the first machinery industry bureau under the municipality, contract work from the market comprised 49 percent of their total task in 1979, and the percentage went up to 73 percent in 1980.

As a consequence of the "six transformations," the machine building industry of the municipality is beginning to be revitalized. These facts fully indicate that resolute readjustment of the orientation of our services is the only way for the machine buildingindustry to seek survival and contend for development in the process of readjustment.

2. Reorganization and Integration are the Efficacious Approach for Implementing Readjustment.

What is the most efficacious approach to the realization of readjustment for the machine-building industry? The most efficacious approach is industrial reorganization and development of economic integration. This has been proved by the experiences in many places as well as by the experience of our own group. Since 1979, with the guidance and support of our higher authorities and in accordance with the principle of economic rationality and specialized cooperation, we have set up at different intervals two corporations, the machine tool corporation, and the meters and instruments corporation, and two general factories, the diesel engine general factory and the valve factory. Included in these corporations and general factories are 14 enterprises, which make up 74 percent of the machine-building enterprises belonging to our bureau. The following methods have been used in reorganizing and integrating the enterprises belonging to us:

//1) Carry out reorganization and integration centered around the development of easily marketable, famous brand, export, and other "first" products.// The advantages of doing this are: basically no additional investments are needed and relatively good economic results can be achieved speedily just be readjusting and rearranging the original plants, equipment, and personnel, and by promoting those products that should be promoted and discarding those that should be discarded, in order to reconstitute new productive force in conformity with the needs of society. For example, electric meters for civil use have been in good demand in our municipality, but the old producing unit was only a small neighborhood workshop, with weak technological forces, poor equipment, meager financial resources, and consequently unable to boost its production batches. The state assigned a plan target of 5,000 meters for 1978, but actually only 300 were produced. The workshop was worried that the good demand for high grade meters would not last long. In contrast to this, an instrument factory of our group had a strong team, but its production task was far short of its production capability. In 1978, surplus stock of 48,000 meters was accumulated. Consequently, the plan target for 1979 was reduced by 60 percent in comparison with the previous year, and the annual task was completed in the first 4 months of the year. The 3d optical factory was another example. It had good equipment and good factory premises, but not many of its products were marketable leaving quite a part of its equipment idle. In the process of readjustment, the electric meter factories were put under our jurisdiction in 1979, and we consolidated the factories. In consequence, production jumped from 500 meters to 30,000 that year. In May 1980, in a further step we merged the factories with the 3d optical factory and the 2d electrical machinery factory to form the instrument and meter corporation, and steps were taken to rearrange the plant buildings, equipments and technological force in a more rational way with the result that the advantages of each factory were given full play. Consequently, 200,000 meters were produced by the year's end, a 550 percent increase compared with the previous year. In the second half of 1980, they took further steps in integration. The "three run" factories (commune-run, street-run and school-run) were also combined into our group. A die-casting, a bakelite and an electric coil factory were set up, to be run collectively by making use of the labor force, plant buildings, and part of the equipment and financial resources of the new partners. It is predicted that a production of about 400,000 electric meters can be achieved this year. In the first quarter of this year, 80,000 meters were already produced, an increase of 220 percent as against the same period last year.

//2) Develop the "superior," and regroup the "inferior."// Through analysis, we came to the understanding that while the machine building industry in the country as a whole was in a distressed situation, locally speaking however, there should be predominant enterprises and predominant products in each locality, and only by developing the "superior" and regrouping the "inferior," could the machine building industry find the largest number of outlets for itself. For this reason, while we undertook readjustment, regrouping, and integration, we paid great attention to assuring help from the "superior" to the "inferior," from the large factories to the small ones, and the state enterprises to the collective. For example, the original first machine tool factory was a comparatively large factory in our municipality, with more than 800 staff and workers and with relatively better techniques and equipments, and it once won a national gold medal prize for its main product, the radial drilling machine, enjoying good marketability both domestically and abroad as well as certain predominance among its fellow producers in the country as a whole. On the other hand, the third machine tool factory, a small factory producing vacuum presses and loading machines was unable to find markets for its products. By the end of 1978, overstocking of products amounted to more than 540,000 yuan and 270 employees were left idle. Sometimes, even shortages of funds occurred for the payment of wages. With the establishment of the machine tool corporation and the subsequent regrouping, the third machine tool factory made the resolute decision of discontinuing production of vacuum presses altogether. Instead, it utilized its equipment, labor force, and plant buildings to produce gear wheels for the radial drilling machine that the first machine tool factory produced. Thus the third machine toold factory which had been on the verge of bankruptcy was saved. In 1979, a profit of 30,000 yuan was made, and in 1980, a profit of 120,000 yuan was made. In the meantime, the production of radial drilling machines of the first machine tool factory was increased by 86 percent in 1980 in comparison with 1979. Again, of the five enterprises that made up the vale general factory, with the exception of the valve factory which was relatively large, the remaining four were all small enterprises run by the local people and of a collective nature. Some were just neighborhood workshops. Most of their products were of poor marketability and they were in a very precarious position. Owing to good flexible work in canvassing sales, the orders taken by the valve factory increased year by year. Finally, it proved difficult to fulfill all the orders by itself. Last year, with the establishment of the valve general factory, cooperation deals were arranged for the four collective valve-making enterprises. As a consequence, work was found for the collective outfits, and development was achieved for the state enterprise. In 1980, production of low pressure valves was increased by 42 percent as against the previous year, while profits went up by 74 percent.

//3) Make great efforts in technological integration with academies, schools and scientific research units to change the backward state of our product technology.// In view of the fact that most of our machine building factories are small in size and weak in technology and research, we are paying great attention to joining our forces with academies, schools and scientific research institutes in other parts of the country in order to enhance the technology of our enterprises and to increase the competitiveness of our products. For example, the first machine tool factory is actively joining its forces with the Huazhong Institute of Engineering and the Wuhan Institute of Engineering to study how to further reduce the production costs of its radial drilling machines so that competitiveness in the market may be improved. Now, preliminary success has already been achieved in improving the design of the old products as well as in the study of value engineering. In addition to this, the pump factory is joining forces with the provincial machine building research institute in developing the partitioned-cell pump; the third optical factory is joining forces with the labor protection institute of the Ministry of Railways to develop a dust cleaner for electric welding; and the insulating material factory is joining forces with the Xian Design Institute to develop a new model of super strainer. We do think that by undertaking cooperation in developing technology and by inserting scientific productive forces into the readjustment of the machine building industry, good results will be achieved in altering the technological backwardness of the machine building industry, speeding up renovation and renewal of products, and the creation of new and powerful productive forces.

As the experiences of the past 2 years indicate, the road of reorganization and integration is in the right direction and gives us outstanding performance. In terms of total annual output value, the four corporations (general factories) which our bureau has set up achieved increases in 1979 amounting to 28.1 percent over 1978, which represents a 15.6 percent above the average growth rate of enterprises of our bureau, and the profits made in 1979 were 104 percent more than in 1978. In 1980, with the exception of the diesel machine general factory which saw a decline in production because of the reduction of the agricultural machinery production task, the other 3 of the 4 corporations increased their annual output value by 37.5 percent compared with 1979 with a growth rate 36.9 percent higher than the average figure for the enterprises of our bureau, and their profits increased by 50.8 percent in comparison with 1979 with a growth rate 34.1 percent higher than the average figure for the enterprises of the bureau.

3. The Key Is for Administrative Organs To Emancipate the Mind and Strengthen Leadership

In the current economic readjustment, the key for activating our economy lies in how the administrative organs of all levels are going to emancipate their minds, strengthen their leadership, and act as promoters of economic integration. In the past 2 years, as a leading administrative organ, we have taken a firm grip on the following aspects of readjustment, reorganization and integration:

//1) Unify understanding, promote reorganization and integration.// Since 1979, most of our bureau have been facing the difficult position of reduced plan targets, insufficient contracts, overstocking of products, and poor marketability of their products. In order to guarantee the growth of the light and textile industry, the machine building industry had to make way for them in regard to financial resources, electricity, raw materials, and so on. Under these circumstances, how can the machine building industry be activated? Through repeated discussions, all members of our bureau from top to bottom have come to the consensus that the only way to overcome the difficulties is to persist in implementing the guideline of readjustment, to develop our advantages and circumvent the disadvantages, to give full play to the predominant factors, and to take the road of integration. It is in the process of readjustment that we are to seek our survival and development. At first, many enterprises had certain confused ideas about reorganization and integration. Some were afraid that production would be thrown into disorder, or their authority would be reduced. Some were accustomed to their "small but complete" outfit without having to rely on others for anything. There were still others who were pessimistic and disheartened confronting difficulties and they did not know what to do. In view of such situations, we called together all the cadres, staff and workers of our bureau and made a serious analysis of the situation, and unified their viewpoints into a consensus through four channels. First, we unified their viewpoints through the channel of the needs of readjustment. With the readjustment of the national economy underway, it was evident that there would be a group of enterprises to be vigorously developed, consequently, there would be also another group which would be operating below capacity. There was even a small number of enterprises which were bound to be eliminated. It was exactly through the process of reorganization and integration that the needs of the readjustment were coped with so that the contradiction of "too much to eat" [production cannot keep pace with supply of materials and planned task] and "too little to eat" [operating below production capacity] was resolved that the [illegible] result of less closing and suspending as well as more merging and shifting [to other modes of production] the enterprises were able to develop together by trimming off the excess to make up for the shortfalls. Secondly, we unified their viewpoints through the channel of the developing competition. As things stood, the market was becoming more and more competitive. In order to survive and be successful in the competition, it is necessary for a corporation to produce products not only of good quality, but also of diverse varieties and with a low price. Besides, production has to be put into operation fast and in big quantities. Again, reorganization and integration are good methods for giving full play to the predominant forces as well as producing things in larger quantities, faster, better and cheaper. Third, we unified their viewpoints through the channel of constant presentation of the good economic pefrormance of the trial points undertaking reorganization and integration. For example, we presented and promoted the experience of integration to be followed by reforms to get ahead steadily of the machine tool corporations. We also presented and promoted the experience of "sales strategy within the factory" adopted by the valve general factory. Through models, we demonstrated the truth of the saying, "Early reform begets early initiative and early integration begets early development." Fourth, we unified their viewpoints through the channel of presenting the common problems faced by certain integrations considering the picture as a whole. Our investigation indicated that the four enterprises belonging to the machine tool corporation wee all equipped with casting and forging facilities, and each was equipped with a maintenance force. In terms of rate of utilizationof capacity, it was only less than 25 percent for the two high frequency electric furnaces, and only about 50 percent for the 560 pieces of equipment installed. This situation was found in every one of the 24 enterprises under the jurisdiction of our bureau. The "small but complete" set-up gave rise to looseness in organization, poor efficiency, redundant technology, and great waste. All this is a negative example of the necessity and importance of integration.

//2) Delegate authority and support reorganization and integration.// We believe that the reorganization and integration of the machine building industry is a revolution. The supervisory organs should emancipate their minds and give their support, and should play the role of promoters instead of playing the role of a stumbling block. As long as it is beneficial to the development of production and the enlivenment of the economy, all rights, without a single exception, that should be delegated, have been delegated. This has enabled the enterprises to exercise their rights and take up their responsibilities in the process of integration, and given them a free hand to carry on their operations. With the commencement of our trial operation of expansion of autonomy at the enterprise level in 1979, we applied to our higher authority to approve our four corporations and general factories as trial points for expanding enterprise autonomy. This gave them freedom and might just like a fish being put back in the water and a tiger being given a pair of wings. For the past 2 years or so, at different intervals, we have delegated the following power to the corporations and general factories: the right to transfer personnel within the corporations and general factories, to appoint and dismiss middle level cadres, to make production plans, to award bonuses, to sell products in excess of production quotas, to make use of the combined production development fund and the supplementary funds for capital assets of the corporations and general factories as well as other rights. This provided them with economic motivation as well as economic means. This closely combined the economic interests of the corporations, general factories, their subsidiary factories, staff and workers. By joining rights, responsibilities, and benefits, it fully motivated initiative.

//3) Strengthen leadership and promote reorganization and integration.// It is an even more demanding requirement of the leading organs to strengthen leadership and promote reorganization and integration. In addition to vigorous support and daring delegation of authority, we must strengthen our leadership. We think that vigorous support does not imply giving up leadership, nor does delegation of authority mean letting things drift. In order to promote reorganization and integration, our bureau has done four things to strengthen leadership. First, we conducted investigation and study, and played well the role of the "red maid" [a go-between in a classical Chinese play] at the initial stage of the reorganization and integration, the party secretary and the director of our bureau on many occasions headed a team of specialists and made investigations as well as analyses on the products, technology, techniques, equipment, and economic plight of the various enterprises so as to ascertain the actual condition of the enterprises according to which programs were made. In the meantime, they personally visited those leading comrades who were confused in thinking or disgruntled so as to help them correct their thinking and make them comprehend the importance, necessity, and urgency of reorganization and integration in the light of the four modernizations. Second, we took a practical and realistic attitude, and guarded against "cutting with one knife." In the process of reorganization and integration, we took different approaches to different features of the enterprises. For example, in the case of machine tool corporations which were characterized by complex technology and strict requirements in making sets, we had integration first and then the reforms, and with the establishment of the corporation we never changed the existing internal relations without careful consideration. What we did was to have a basic "unification" first, undertook internal cooperation within the group, and then by stages and by steps made our way towards division of tasks by specialization. In the case of enterprises that produced simpler products and utilized similar technology, we unified while we made readjustments, and went ahead faster. Third, we abided strictly by the policy, and guarded against "eating out of a big pot." In the process of reorganization and integration, we made a strict distinction between the system of ownership by the whole people and the system of ownership by the collective. We did not change the economic nature of all enterprises that joined the corporations and general factories. Within the corporations, separate accounts were kept and independent accounting was made for the entities under the system of ownership by the whole people and those under the system of collective ownership, and no transfers were allowed among them. When a transfer was made, compensation had to be made, or rental paid. As for transfer of labor, the parties concerned had to settle for the services made. Wages and welfare were kept to the original set-up. Fourth, offering services to achieve coordination and rendering help to the basic level organizations. The leading cadres of our bureau went down to the grass-root units of the corporations and general factories, and conducted study with the people there in respect to production, technology, finance, management and other concrete problems, and offered them ideas and proposals. Besides, they selected and appointed members to the leading group of the corporations and general factories as well as their subsidiary factories in order to actively create the conditions for the promotion and constant development of reorganization and integration.

GENERAL

BRIEFS

GUANGDONG ECONOMIC TRIBUNALS--Various places in Guangdong Province have extensively set up economic tribunals to uphold socialist economic order and defend the four modernizations. At present, the intermediate people's courts of all prefectures and municipalities have set up economic tribunals and 60 percent of county people's courts have set up economic tribunals. These tribunals have seriously handled economic cases and disputes. According to statistics, by the end of May this year, the province had handled 717 economic cases, equal to the total number of last year. The economic disputes included disputes on agreements, transactions, description of goods, payment of goods and breach of contracts. [HK180705 Guangzhou Guangdong Provincial Service in Mandarin 1100 GMT 20 Jul 81]

HEILONGJIANG ECONOMIC CONFERENCE--The Heilongjiang provincial work conference on utilization of stocked goods concluded 14 August. It urged all provincial enterprises and establishments to make wise use of stocked goods such as metal products, machinery, chemical, light and industrial products and building materials, stating that no enterprises are allowed to buy these goods without the approval of responsible departments. In mid-July, the provincial economic and planning commissions and other departments concerned jointly issued a circular urging wise use of these goods. The conference disclosed that in 1980 some 900 million yuan worth of goods were in stock; rolled steel in stock totaled 100,000 tons. 'WEN WEI PO' ON DAM CONSTRUCTION ON CHANGJIANG

HK220517 Hong Kong WEN WEI PO in Chinese 22 Aug 81 p 3

[Feature article by correspondent Ou Ping-Chiang: "The Construction of a High Dam in the Three Changjiang Gorges--Interview with Wei Tingzheng, [7614 1694 6927], Deputy Director of the Changjiang Basin Planning Office"]

[Text] The thousand-li Changjiang, with its distant source and long stream, nurtured Chinese civilization. Its swinding waters form a natural channel for navigation from the hinterland to the sea. Nevertheless, the Qutang, Wu and Xiling gorces are in the middle reaches of the Changjiang, which link Sichuan and Hubei. Although people marvel at the exotic rocks and precipitious cliffs, the currents are rapid in the three gorges, and there are many sharp bends and dangerous shoals. Over the past many years, they have gobbled up numerous ships and people and have become forbidding trips for boatmen.

In particular, the Xiling gorge in Hubei is infested with shoals. Since liberation, numerous demolitions were carried out and the channel has been greatly improved. However, during the dry season, ships still have to be very careful when they sail pass.

Rebuild the Three Gorges Into a Reservoir [subhead in boldface]

"To thoroughly improve the channel in the three gorges, where there are numerous shoals and rapids, we must build dams across the river to form a 'reservoir in the three gorges.' This is in fact a good method to utilize in a comprehensive way the waterpower resources in the Changjiang." Wei Tingzheng, deputy director of the Changjiang Basin Planning Office, zestfully talked about the grand plan to tame the Changjiang when he was recently interviewed by this correspondent in Yichang.

He noted: Since liberation, the state authorities have attached great importance to harnessing the Changjiang. During the 1960's, water conservancy experts gathered in Chengdu and studied plans to build dams on the Changjiang. They also submitted a report to Premier Zhou.

China's water conservancy experts held that to completely improve the three gorges and turn danger into safety and bane into boon, we should build a high dam across the river in the Xiling gorge to raise the water level and conserve water. We should then build another low dam somewhere near the lower reaches as a supplementary project for the entire construction project in the three gorges--to be used for power generation and improvement in shipping transport.

However, because of the huge costs of the construction project in the three gorges, and since we are restricted by our economic conditions, there was a change in the construction plan. The order "first build a high dam and then build a low dam" was reversed; hence the construction of the Gezhouba dam was launched. Construction began in 1970 but was once suspended for technical reasons from 1972 to 1974. The construction project was completely resumed during the second half of 1974 and the first stage of the project was completed this year. It has now started generating electricity and is open to navigation. We have continued with the second stage of the project and it is estimated that it will be completed by 1986. By that time, this major dam with a total length of 2,561 meters will be able to display its greatest usefulness.

Two Points of Controversy Concerning the Construction of the Major Dam [subhead in boldface]

When exactly will the construction of the major dam in the three gorges begin? This is what people are most concerned about.

According to what was disclosed by Wei Tingzheng, they are still debating the issue and have not reached any decision.

There are mainly two points of emphasis in the controversy:

1) It involves a huge investment amounting to more than 10 billion to 20 billion yuan renminbi. Since our national economy is currently in a period of readjustment, it is probably inappropriate to launch a construction project involving such a huge investment.

2) It involves extensive migration of the population. Since the water level in the three gorges will be raised, about 700,000 people now living in the urban and rural areas, including Chongqing, near the river banks in a section of the channel will have to move somewhere else, and about 600,000 mu of farmland will be inundated. It is thus open to question whether the construction project is worth launching.

These two points are indeed big problems that have hindered the construction of the major dam in the three gorges. Nevertheless, after detailed prospecting and planning, water conservancy experts have made specific suggestions concerning the construction of the major dam in the three gorges. There is a choice of two sites for the construction of the dam: 1) Sandouping in the Xiling gorge; and 2) Taipingxi, which is 7 kilometers up the river from Sandouping.

The Estimated Capacity of the Power Generators Is Quite Huge [Subhead in boldface]

The major dam in the three gorges will be 200 meters high. It will raise the water level by 130 meters, to reach the same level as at Chaotianmen in Chongqing, where the Changjiang and Jialing Rivers converge. The dam will hold 70 billion cubic meters of water and form a big reservoir.

The total installed capacity of the electric power generators of the major dam of the three gorges, as currently designed, will be 25 to 30 million kilowatts. They will be able to generate 111 to 126 billion kwh annually, equivalent to more than one-third of the total electricity generated in the whole country last year.

The dam in the three gorges is well situated. It is 1,200 kilometers from Beijing, 1,100 kilometers from Shanghai and 1,000 kilometers from Guangzhou. Powerful electric current can be transmitted through high-voltage electric cables to most of the areas in east and south China.

China is rich in waterpower resources. According to an estimate by the ministry of electric power generators in theory is over 700 million kilowatts, and there are 380 million kilowatts of potential capacity to be tapped. However, the total installed capacity of the hydroelectric power stations throughout the country in 1980 was 20.2 million kilowatts, only 3 percent of the total potential installed capacity, and the annual electric power generated was 58.2 billion kwh.

In spite of that, China's electric power generation ranks sixth in the world after the United States, the Soviet Union, Japan, West Germany and Canada, while its hydroelectric power generation ranks fifth in the world. It can thus be seen that there are broad prospects for China's hydroelectric power generation.

The advantages of hydroelectric power generation are that it uses the natural sources of water, which can be used continuosuly and will never be exhausted. The disadvantages are that building a hydroelectric power station needs more investment than a thermal power station, it takes longer to recover the capital invested, hydroelectric power stations are usually further away from the industrial areas, and so on.

China is a country with vast territory and abundant resources in various aspects. The major dam in the three gorges can generate high economic effect, and its construction is quite necessary.

GUANGDONG, FUJIAN SPECIAL ZONES DISCUSSED

HK200735 Hong Kong WEN WEI PO in Chinese 19 Aug 81 p 2

["Guangdong and Fujian Adopt 10 Measures to Develop Construction of the Special Economic Zones"]

[Text] Beijing, 18 Aug (ZHONGGUO XINWEN SHE)--Recently, Guangdong and Fujian Provinces have further put into effect the special policies and flexible measures in accordance with the spirit of the instructions of the Party Central Committee and the State Council and have boldly undertaken anything that is in conformity with the general and specific policies of the state and facilitates the readjustment and development of the economy of the two provinces and of the whole country. At the same time, they abide by a strict scientific attitude and make efforts to advance smoothly.

The main content of the special policies and flexible measures that are being carried out in Guangdong and Fujian Provinces are as follows: 1. Measures to be more open to the world including active utilization of foreign capital, introduction of suitable advanced technology and scientific management and expansion of foreign trade; 2. Freer domestic and foreign policies including better use of the law of value and other economic levers to make the economy more lively; 3. Expansion of the power of the two provinces in the fields of economy, personnel, and local legislation as well as more independence for enterprises.

The two provinces may fully develop their economic independence under the conditions of adhering to the following five conditions: (1) Adhering to the fundamental principles of the socialist road, the people's democratic dictatorship, that is, proletarian dictatorship, the leadership of the Communist Party and Marxism-Leninism-Mao Zedong Thought; (2) observing the unified general policies of the state; (3) obeying the guidance of the unified planning of the state and the comprehensive balance of the whole country; (4) fulfilling the tasks alloted by the state; (5) persisting in unity of action in external transactions.

Concerning the problems of the systems of planning, finance, banking and foreign trade in the two provinces, there are the following measures:

--Regarding the planning system, the planning of the province and the localities should be combined with that of the province as the dominant factor under the guidance of the general and specific policies and planning of the central authorities;

--Financially, the financial responsibility system should continue to be carried out. Under the prerequisite of fulfilling the alloted financial targets of the provinces, they have the power to arrange their finance independently;

--The provincial bank branches should play the role of local banks. The management independence of the provincial banks should be expanded on the basis of the existing system and structure of management. Under the prerequisite of ensuring the fulfillment of the alloted amount of foreign exchange that should be handed over to the state, they have the independence to use what is left of the foreign exchange in accordance with the foreign exchange management regulations of the state;

--The independence of the two provinces in foreign trade will be enlarged. The export plan of the foreign trade of the two provinces should mainly be made by the provinces on their own and then be incorporated into that of the Ministry of Foreign Trade and included in the state plan. The local foreign import should be planned by the provinces and reported to the relevant departments so as to be put on record there. The two provinces should make full use of their respective strong points to develop economic and technological cooperation with foreign countries. The main material and parts imported by the two provinces for processing export goods will be exempted from import duty, but they will be taxed if the goods processed are transferred to the domestic market.

The Concrete Content of the 10 Measures

There are the following 10 measures for developing the construction of the special economic zones:

(1) The planning and construction of the special zones should be carried out in line with their local conditions and attention should be paid to the practical effects and to laying particular emphasis on developing certain sections of the economy. The Shenzhen and Zhuhai special zones should be developed into comprehensive special zones with the diversified economy of industry, trade, agriculture, animal husbandry, housing and travel. The Xiamen and Shantou special zones at present, should be developed as zones mainly for processing of foreign goods and with the development of trade and other economy at the same time.

(2) The customs should grant special preferential tariffs to goods imported into the special zones. After the demarcation lines between special zones and nonspecial zones are under strict administration, all the means of production and consumer goods imported to be used in the special zones for which permission has been granted will be exempted from customs with the exception of cigarettes and alcohol which should be taxed at half of the lowest rate and a few kinds of other goods, which should be taxed according to the relevant regulations. Goods transported from those zones to other areas in the country should be taxed according to the general regulations on importation. Before the demarcation lines are established the temporary customs regulations remain in force.

(3) Entry and exit procedures will be simplified to facilitate the entry and exit of people. All the special zones have the power to inform the visa office to issue visas to foreigners and overseas Chinese who want to enter the special zones. For those who have to come and leave frequently, multiple entry visas good for not more than 1 year will be issued.

(4) All the staff and workers of the enterprises in the special zones will be employed under contract. The enterprises will have the right to decide on matters of employment, probation and dismissal and the remuneration system of low wages and high allowances will be changed step by step. Wages should consist of two component parts: basic and floating. Under the unified arrangement of the zones, pensions and social welfare should be eventually introduced.

(5) The special economic zones should conduct their foreign trade independently in the general direction set by the state's unified policy for foreign trade. Commerce should be mainly in the hands of state enterprises. But the special economic zones should also be allowed to set up certain joint commercial ventures with foreign firms. Import of necessary commodities should be permitted.

(6) At present, Reminbi is the main currency used in the special economic zones. The use of foreign currency is limited only to specified areas. The People's Bank should vigorously make a study of the feasbility of the issue of a special currency for Shenzhen. Chinese banks registered in Hong Kong will be permitted to set up branches in the zones. Step by step a selected number of foreign banks will be allowed also to have their offices there. The State Foreign Exchange Control Administration will set up branches in these zones.

(7) Active measures should be adopted to raise funds for the construction of the special economic zones. On the one hand foreign funds should be used as one of the sources of funds. On the other hand, for the funds in Reminbi needed for the construction of the zones, an appropriate amount of additional loans should be allocated to them as far as conditions permit.

(8) Airports, harbors, ralways and telecommunications facilities should be allowed to develop with foreign investments. These can be run by the zones or in cooperation with foreign enterprises. But they will have to assume sole responsibility for their profits or losses.

(9) To speed up the development of the various undertakings in the construction of special zones, certain special bylaws and regulations should be drawn up for the zones. A suggestion has been made to the Standing Committee of the National People's Congress to pass an act empowering the standing committees of the people's congresses of Guangdong and Fujian Provinces to draw up these bylaws and regulations and report them to the Standing Committee of the NPC and the State Council to be put on record.

(10) The zone administrations should be streamlined. They should be given sufficient power to handle problems and coordinate the relations between various departments independently. To ensure law and order in the zones and strengthen the administration of the borders, the security work of the zones should be vigorously strengthened. The demarcation lines between special zones and nonspecial zones should be established as soon as possible and they will be patrolled by the frontier guards and police forces.

PREDICTION OF WORLD COMMODITY MARKET PRICES

HK190316 Hong Kong WEN WEI PO in Chinese 18 Aug 81 pp 1-2

[Dispatch from Beijing: "Foreign Trade Ministry Research Office Predicts International Market Trends: World Grain Prices To Show Big Rise, Oil Crisis To Ease"]

[Text] The Foreign Trade Ministry Research Office has recently made an analysis of the development trends of several major commodities in the international commodity market in the 1980's and predicts that their prices will rise.

1. The basic situation of world grain at present is that production lags behind the increase in consumption and the grain reserve level is very low. The world grain supply in the 1980's will be unstable. It is estimated that the Soviet Union will maintain a relatively large quantity of grain imports. Grain imports of most Third World countries also show signs of increase. It is estimated that grain prices in the 1980's will fluctuate at a relatively high level. If serious failure in grain production occurs in the main grain exporting and importing countries, grain prices will show a big rise.

2. Oil will remain the chief source of energy in the 1980's. Because the amount of oil recovered has been greater than the amount of newly proven reserves in the last few years, oil exporting countries may continue to adopt the policy of limiting or reducing production. Moreover, the Middle East situation is unstable. The supply of oil will also be very unstable and the general trend of oil prices will be a continuous rise. However, the Western countries have recently made some headway in saving energy, exploiting energy resources and developing new energy resources. It is predicted that the situation of oil supply and demand will ease and the rise of oil prices will not be as great as that in the 1970's.

3. It is estimated that, because of the slowdown of economic growth rates in the capitalist countries, the development in production of substitutes and the increase of production costs in mining and smelting, the increase in production and trade of nonferrous metals in the 1980's will be rather slow. On the whole it will remain at the level of the 1970's with an average increase of 3 to 5 percent. The production of lead, magnesium and titanium may increase slightly faster and the production of tungsten, antimony and tin may increase more slowly than this. What is worth noting is that the present international situation is turbulent. The military expenditures of the United States, the NATO countries and other European countries have all increased and the amount of strategic materials and

goods cornered will also increase in varying degrees. Therefore, there may be a relatively big price rise of nonferrous metals in the 1980's depending on the development of the situation.

4. In the 1980's, competition in the world textile market will even be more acute. The number of exporting countries and the amount of textile goods available for export will also increase. But trade protectionism will be further strengthened and the rate of increase of textile goods will be slower than that in the 1970's. The basic market trend is to upgrade the products and to produce products of greater variety and superior quality. In order to adjust to the trend of market development, all main textile exporting countries and regions are striving to reform the structure of products as a means of raising their competitive capacity.

5. The trend of the market development of light industrial consumer goods is similar to that of textile goods. Expensive goods, goods of greater variety and superior quality will be required. Daily-use electrical products will develop in the direction of saving energy and a higher degree of automation. The demand for consumer goods such as articles for traveling, cosmetics, articles for recreation and physical culture, daily-use electrical appliances, furniture, kitchen utensils, pottery and porcelain, toys and so on will have a relatively great increase. The trend of development in handicraft articles will be the integration of daily-use articles with those of an artistic nature. The trend of trade in light industrial consumer goods and handicraft articles in the 1980's will be one of a steady increase.

6. Machinery products account for slightly less than one-third of the total international trade volume and three-fifths of the world's total export volume of finished products.

The development of high-grade precision machinery products in the 1980's will be faster than that of elementary and ordinary machinery products. Trends which are worth noting are: 1. Investment in equipment for producing products which save energy and raw materials is still increasing. Orders for equipment such as machine tools for developing small-size and light automobiles which consume less oil and pollute less have increased in large numbers. 2. The demand for equipment for developing new energy sources continues to increase.

3. Signs of revival of the shipbuilding industry have appeared. 4. There is an increasing need for specialized industrial machinery and complete sets of equipment, such as machines for hydraulic power station, cereal processing, foodstuff processing, light industry, civil engineering, and so on.

It is estimated that in the 1980's the market for machinery products will extensively develop and the prospect is bright. In particular, the demand for ordinary machinery by importing countries will increase remarkably.

FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

'JINGJI YANJIU' ON CHINA'S SOCIALIST SYSTEM

HK290800 Beijing JINGJI YANJIU [ECONOMIC RESEARCH] in Chinese No 7, 20 Jul 81
pp 3-10

[Article by Xu Dixin [6079 3321 2450]: "On China's Socialist System"]

[Text] In studying the "resolution on certain questions in the history of our party since the founding of the People's Republic of China," I deeply felt that due and clear deliberation should be made on this yatter, that is deciding, "whether or not the socialist system has been established in China." I would like to expound on this subject from the economic angle.

Lenin once briefly pointed out: A socialist system has two fundamental characteristics: one is public ownership of the means of production and the other is that the principle of "to each according to his work" is practiced in regard to consumer goods. Are these two fundamental characteristics part of China's social economic system?

I. On Socialist Public Ownership of the Means of Production

Socialist public ownership of the means of production is the economic basis of a socialist society. In the early days following liberation, with the confiscation of bureaucrat capital of the big four families of the Kuomintang, nationwide socialist state-owned economy was established which was represented by the state power of the people's democratic dictatorship under the leadership of the proletariat. The socialist state-owned economy encompassed the major proportion of the modern industrial, mining and transport enterprises and became the mechanism of the whole national economy. In the winter of 1952, through various ways and means the state integrated those enterprises built with foreign investments which had been in operation for a long time into the socialist state-owned economy. By the first half of 1956, with the realization of the joint state-private ownership throughout the trades and professions, the capitalist industry and commerce run by the former national capital were transformed into state-run enterprises under the system of ownership by the whole people. It can be said that in the 1950's, or more precisely in 1956, the state-owned economy under the system of ownership by the whole people was established in the main. Of course, judging from the present state of affairs, the state-run enterprises formed by confiscating bureaucrat capital, taking over foreign capital investments in China and transforming the national capital comprised only a small part of state-run enterprises. Most of the state-run enterprises were set up by the Chinese people over the past 2 decades or so. These enterprises are owned by the whole people and the economy is socialist in nature.

At present, China's enterprises under the system of ownership by the whole people have taken the form of state-run enterprises. That is to say, representing the entire people. The state under the people's democratic dictatorship runs and manages the enterprises under the system of ownership by the whole people. There is a difference between the emergence of socialist ownership of the means of production and private ownership of the means of production. History tells us that private ownership of the means of production occurred and grew spontaneously but socialist ownership of the means of production (including ownership by the whole people and the collective) was established through the socialist revolution launched by the proletariat and through the expropriation of enterprises. Since socialist ownership of the means of production (in particular, ownership by the whole people) was established by the state power under the people's democratic dictatorship, then, it is inevitable both in theory and practice for the state which represents the people to manage and run the newly established enterprises under the system of ownership by the whole people. It is only natural that ownership by the whole people is not necessarily in keeping with ownership by the state entirely. In the future, after the state perishes, the problem of the state representing, managing and running enterprises owned by the whole people will not exist. In China today, the state-run enterprises in some localities or even those under the jurisdiction of some ministries are sticking to the departmental interests and ignoring the interests of the whole. This not only infringes upon the nature of the state-run enterprises but also seriously infringes upon the nature of ownership by the whole people. To put it another way, they have lost to a certain degree the nature of socialist ownership by the whole people. This is a problem urgently demanding our prompt study and solution.

Practice over the past 30 years has proved that it is undoubtedly logical for the state power under the people's democratic dictatorship to manage and run the enterprises under the system of ownership by the whole people. Of course, there are contradictions between the state and enterprises. In managing enterprises, if the state policies stem from over-centralization, the decisionmaking power of enterprises will be weakened or even abolished, thus causing the enterprises to take a completely passive position, hampering their flexibility and dampening their enthusiasm. In maintaining its leadership over enterprises, if the state takes in consideration the roles of objective natural and economic laws and acts upon administrative measures alone in doing things, we will not achieve the deserved economic results in the socialist production and socialist construction, resulting in great waste to the enterprises and even to whole departments. These defects have dawned on everybody. The party and the state are adopting measures to improve the system of the state-run enterprises and rectify the management of state-run enterprises.

Regarding China's public ownership of the means of production, apart from ownership by the whole people, there is the ownership of the means of production by the collective which are formed by the working people. The major component of collective ownership was the rural collective agriculture. Over the past 2 decades or so, in our socialist collective agriculture, we adopted a system of three-level ownership by the commune, the production brigade and the production team, with the production team as the basic accounting unit. The overexpanded power of the commune and the production brigade hampered the decisionmaking power of the production team and dampened the enthusiasm of the commune members for production. In the past 2 years, in many places the production teams implemented the system of "fixing output quotas for households." For this reason, some people hold that there is a retrogression in China's socialist collective agriculture. The facts have negated this claim. "Taking full responsibility for fixed farm output quotas" is a type of production responsibility system and is not private ownership of the means of production. Under the leadership of the production teams, "the households responsible for the fixed farm output quotas" sign contracts on their output quotas on rewards for exceeding the contracts and punishments for not fulfilling them. "The households responsible for fixed farm output quotas" only have the right to use the land; they do not own the land. This proves that the production responsibility system characterized by "taking full responsibility for fixed farm output quotas" is not a political negation of the agricultural collective ownership but on the contrary, it takes the collectively-owned land as a prerequisite. This also shows that there exists a fundamental difference between the production responsibility system characterized by "taking full responsibility for fixed farm output quotas" and "land being parcelled out to peasant households." "Land being parcelled out to peasant households" means quite clearly individual farming and sabotages agricultural collective ownership. This must be resolutely opposed: The production responsibility system characterized by "taking full responsibility for fixed farm output quotas" is a kind of labor organizational form conducive to developing production. This labor organizational form is a political negation of the past practices of "doing things in a massive and unplanned way" and "being on duty but doing on work," and a political negation of the "approximate workpoints" which was in violation of the principle of "to each according to his work." The practice in the past 2 years has shown that the present production responsibility system is characterized by "taking full responsibility for fixed farm output quotas" suits the current level of development of agricultural productive forces and the level of consciousness of the masses of commune members. Obviously, this form of "taking full responsibility for fixed farm output quotas" is not a permanent system. At present, in some places "the households responsible for fixed farm output quotas" are being integrated to develop agriculture and sideline production due to lack of manpower. In order to continue to arouse the peasants' enthusiasm for production and enable the peasant to become rich, we should not push this integration too quickly. With the development of agricultural production and rural diversified economy, the spontaneous integration of "the households responsible for fixed farm output quotas" seems to be a trend of development. However, this trend is unlikely to be supervised from the top to bottom and a mass movement "rolling on at full force."

In the past 2 decades or so, we treated collective ownership differently. We regarded ownership by the whole people of the means of production as being far superior to collective ownership of the means of production in respect to the degree of public ownership. This was because the degree of collective ownership was limited to a smaller scope, to a specific collective, while that of the ownership by the whole people was owned by the working people of the whole country. Proceeding from this understanding, they emerged the problem of the so-called "transition." Under the prerequisite of maintaining the three-level ownership by the commune, the production brigade and the production team, with the production team as the basic accounting unit, the production team should undergo a transition to the production brigade and the production brigade to the commune, and the commune should undergo a transition to ownership by the whole people from collective ownership. By that time, there will be sole ownership by the whole people throughout the country. From a long-term point of view, before entering communism, it is an inevitability to realize sole ownership by the whole people. But, today if we promote rapid changes in the matter of ownership and make preparations for realizing sole ownership by the whole people irrespective of the level of development of the rural productive forces, the "paupers' transition" which amounts to sabotaging the rural productive forces will inevitably occur. This "paupers' transition" was in essence an important form of the "stirring up of winds of communism." When the conditions of the level of development of the rural productive forces and the level of consciousness of the masses of commune members are not ripe enough to undergo a "transition," we indulge in "transition" by resorting to coercion and commandism. How can this practice not arouse the resentment of the masses of commune members, resulting in their killing hens, selling cows and felling trees?

Practice proves that taking full responsibility for their own profits and losses by the enterprises under the system of collective ownership is definitely not the so-called revisionism. Regarding the development of the socialist national economy, it is far better than the system in which the state-run enterprises eat from the same big rice pot with iron bowls. "Taking full responsibility for one's own profits and losses" is a kind of responsibility system in production (management) whereas eating from the same big rice pot is the opposite a contradiction with responsibility system in production. Therefore, if all enterprises under the system of collective ownership are advanced into the ranks of state-run enterprises which is "eating from the same big rice pot," this will create an incalculable burden to the socialist national economy. Of course, those who stick to indulging in "paupers' transition" and the early realization of sole ownership by the whole people are small in number. But, the bitter experiences have caused people to maintain vigilance on this issue. I hold that ownership by the whole people and collective ownership will coexist for a considerable period. This suits the level of development of productive forces and that of socialist consciousness of the masses of people at the present stage of our country. Letting the two systems of ownership by the whole people and collective ownership exist side by side for a long period of time will benefit the development of our social productive forces and improve the material and cultural life of the residents of both urban and rural areas, and also end the "paupers' transition" which harms the rural productive forces.

As for ownership of the means of production, for a number of years ahead, we should not only vigorously develop collective ownership characterized in taking full responsibility for one's own profits and losses, but also appropriately develop individual economy, that is, we should develop service trades, repair and renovation service, individual commerce and the production of labor-intensive and traditional handicrafts. The more modernization develops, the comparatively less and less it needs manpower (unskilled labor in particular). Providing young people awaiting jobs has become a heavy burden to the state, let alone the rapid growth of our population. It is important to relax the policies concerning individual economy and open up avenues of employment to the young people awaiting jobs, to provide workers for those trades which need a sizable number of workers and to facilitate residents in urban and rural areas. Appropriate development of the individual economy will become a necessary complement to the socialist economy instead of doing harm to the collective economy which holds the dominant position in the national economy.

In order to realize the socialist modernization drive, we must uphold the principle of self-reliance and carry out reform and rectification among the existing 350,000 enterprises so as to improve their technical level, ensure product quality, raise the management level, do a good job in business accounting and obtain the maximum results at minimum costs. Along with this, it is very necessary to use foreign capital and form joint ventures with Chinese and foreign investment. This is a way for us to import new techniques from abroad which deserves our special attention. Besides, we have set up economic zones in some coastal areas such as Shenzhen, Zhuhai and Shatou in Guangdong Province and Xiamen in Fujian Province. Some people worry: This is the restoration of foreign capital in China and the revival of old China's "concessions." In my opinion, these worries are unnecessary. Facts will prove that the sovereignty of the present economic special zones is in the hands of our country and not in the hands of the foreigners like it was in old China. Facts will show that these "joint enterprises with Chinese and foreign investment" are state capitalism of a special form; the "privately-operated enterprises" set up in the special zones with the approval of our government are capitalist enterprises under the management and restriction of our government. They are state capitalist in nature. It is only natural that those putting up the foreign investment in joint ventures want to exploit surplus value. They are not philanthropists. If there are no good prospects for profits, they will make investments. However, in order to absorb foreign capital and introduce advanced technology from abroad, a definite amount of exploitation is tolerable. It is in nature a policy of redemption. The joint ventures with Chinese and foreign investment and privately-operated enterprises with foreign investment occupy only a small proportion in the whole national economy and the redemption they earn also comprise a small proportion in the national income. Therefore, the establishment of economic special zones and the importation of foreign capital will never shake our socialist economic system.

Since the operation of some individual economy is allowed in cities and towns and foreign investment is permitted in our country to form joint ventures with Chinese side and operate private enterprises, it is China's socialist public ownership (ownership by the whole people and collective ownership) that holds a leading position and has the absolute advantage in our national economy instead of them. The socialist ownership of the means of production has negated the exploitation of man by man (as part of the redemption, we should deal with it separately) and has become the prerequisite for the interrelations of mutual aid and cooperation established in the process of production, and has become material conditions for developing the national economy in a proportionate and planned way. Of all these, which points are proving that China today is not a socialist country? If we take the individual economy and the joint ventures with Chinese and foreign investment or the privately-operated enterprises a basis for negating the fact that China's socialist public ownership of the means of production holds an absolute predominance in the whole national economy, if we take the enlargement of decisionmaking power of state-run enterprises and the adoption of the production responsibility system characterized by "taking full responsibility for fixed farm output quotas" in the rural areas as a basis for deciding that China is moving back from socialism to capitalism, or even doubt that whether China is a socialist country, this will be a denial of objective facts and a distortion of our socialist system.

II. On the Principle of To Each According To His Work

Another fundamental characteristic of socialist society is the principle of to each according to his work. Under the socialist system, the implementation of the principle of to each according to his work in the distribution of the means of consumption is based on socialist public ownership of the means of production. In the capitalist society, the laborers have nothing; they have to sell their labor power as a commodity to the capitalist. The wages earned are set by the capitalists for their labor power.

The surplus value squeezed by the capitlaists from the process of production by the laborers is distributed among the industrial capitalists, commercial capitalists and banking capitalists in the form of profits and interests according to the amount of capital. Needless to say, the working people receive no portion of these whatsoever. Only on the condition of the abolition of the capitalist system and the realization of public ownership of the means of production, can people depend on their labor but not on property to obtain the means of consumption. Under the principle of to each according to his work, all people can equally use a standardized yardstick--labor--to measure the quantity and quality of labor one provides to society. That is to say, the principle of to each according to his work is an inevitability in the field of distribution of socialist ownership of the means of production.

Many of our comrades have affirmed the socialist principle of to each according to his work. At a stage before 1950, China's trade union and its affiliated organizations and the industrial departments concerned once adopted reforms of the wage system (special attention was paid to piece rate wages), thus realizing the principle of to each according to his work. It was a pity that not long after the implementation of this socialist principle of distribution, it was pounded by the "leftist" ideology. The "leftist" ideology held that the principle of to each according to his work took unequal bourgeois rights as principles and therefore it held that the principle of to each according to his work would inevitably create differences among the people--some would be rich while others were poor. The Lin Biao and Jiang Qing counterrevolutionary cliques more wantonly vilified the principle of to each according to his work and glorified egalitarianism. They looked upon the principle of to each according to his work as capitalism while egalitarianism as socialism. Due to the longstanding propagation, even after the smashing of the "gang of four," egalitarianism was still playing a disruptive role comprehensively and profoundly in various fields.

Egalitarianism is not the socialist principle of distribution and not the inevitability of socialist ownership of the means of production. In order to develop China's socialist national economy and arouse the enthusiasm of the masses of working people for socialist production, we must repudiate the harmfulness of egalitarianism in a comprehensive and long-term way. At the same time, we must repeatedly explain that only when the principle of to each according to his work is practiced, can the superiority of socialism be displayed.

III. Views on Some Viewpoints

As mentioned above, after the founding of state power under the people's democratic dictatorship, the confiscation of the land of the feudal landlords and organizing the peasants to whom land was distributed, and the realization of socialist transformation of agriculture, handicrafts industry and capitalist industry and commerce, our country entered the socialist society. But, today as we have been a socialist society for more than 2 decades, there are still some comrades who have raised an objection to the nature of China's society and its entering of the socialist society.

1) An argument holds that only when the highly socialized production and the direct distribution of products among the people are realized, that is to say, only on the condition that commodities and money are abolished, can such a society be called a socialist society. However, in our country, the state-owned economy under the system of ownership by the whole people or the collectively owned economy of the working people are still producing commodities and need commodities and money. According to this argument, our country cannot be regarded as a socialist society. Can this argument hold water?

Concerning social production and social circulation after the abolition of the capitalist system, Marx once predicted that commodities and money would exist no longer. In Volume 2 of "Das Kapital," Marx wrote: "In the production under the system of public ownership by society, money-capital will no longer exist. The society distributes manpower and the means of production among the different production departments. The laborers may get paper certificates by which they can draw a portion equal to their labor time from the social reserves of consumer goods. These certificates are not money. They are not circulated." Commodities and money all belong to historical economic category. They naturally cannot escape from the historical law of coming into being, developing and passing away. For this reason, the elimination of commodities and money predicted by Marx will come true some day. But, we must never deny the concrete conditions of social production and treat this prediction of Marx' in a dogmatist manner.

After the October revolution (in 1919) Lenin made a statement on the fate of money. He said: "Can money be eliminated at once? It cannot. Long before the October revolution, the socialists had said that money could not be eliminated at once, and our personal experiences have proved this." He later said: "For the time being money will remain, and remain for a fairly long time in transition period from the old capitalist system to the new socialist system." ("Collected Works of Lenin," Vol 29, p 321) Stalin made a firmer assessment on this matter. He said: "So that's how it is. On the condition of our (meaning the Soviet Union,--the following quotation refers to the same) socialism, the economic development was not carried out in a transformative way but in a gradually changing way. Old things were not simply eliminated in a neat and tidy way but they changed their nature to suit new conditions and they kept their basic forms. Instead of eliminating old things, new things infiltrated into old things, changed their nature and functions but did not destroy their forms, instead, used their forms to develop themselves. So is the case of not only commodities but also money in economic circulation and even so is the case of banks." (Stalin: "Problems of the Soviet Economy," p 42) According to these quotations from Stalin, in the socialist system, commodities and money are things which have changed their former nature and functions and serve the socialist economy. We must implement the principle of to each according to his work, because the double-track system of socialist ownership of the means of production will exist for a long time and the production of social material wealth cannot in a period of considerable length reach the state of to each according to his needs. With the immense variety of consumer goods needed by the members of society, to exercise direct distribution of products will bring innumerable difficulties. Therefore, in the socialist society, commodities and money will exist for a fairly long period of time instead of a short one. If attempts are made to abolish commodities and money in an over-simplified way, this will bring incalculable disorder and disaster to the socialist national economy. Are these disorder and disaster merely predictions? Haven't they been verified by actual practice in certain places? In short, the elimination of commodities and money are not the fundamental characteristics of the socialist society. The utilization of the forms of commodities and money is not a political negation of socialist public ownership of the means of production. In our country, now that the socialist public ownership of the means of production has been established and commodities and money have been used to serve the socialist economy, then, can the argument that takes the existence of commodities and money as the basis for doubting our socialist system hold water?

2) Another argument holds that only in the countries where capitalism is highly developed can the socialist revolution be carried out and the socialist system be established. But before liberation, China was in a state of dilapidated semi-colonial and semifeudal society with extremely low level of development of productive forces, therefore, it was necessary to fully develop capitalism before the introduction of socialism. This viewpoint is nothing new. The advocates of the second international (even China's liquidationists such as the Troskiyist Chen Duxiu) said this. To oppose the socialist revolution of the Russian working people, the advocates of the second international raised the so-called "the Russian productive forces have not developed to such a degree as to realize socialism." In appearance, they seemed to uphold the law that the relations of production must suit the level of development of the productive forces, but in essence, they were serving the rule of the bourgeoisie and sabotaging the socialist revolution of the Russian proletariat and working people. In his "Problems of the French and German Peasants," Engels clearly said: "Before realizing this change, we need not wait for the time when the outcome of development of capitalist has been manifested in extreme form everywhere and when the last one of small handicraftmen and small farmers has become the victims of capitalist mass production." ("Selected Works of Marx and Engels," Vol 4, p 312) Lenin developed the ideas of Marx and Engels, pointing out that the proletariat could use the established worker-peasant alliance to seize political power and then rely on the proletarian political power to develop the economy and culture, and thus realize socialism. He said: "If a definite level of culture is required for the building of socialism (although nobody can say just what that definite "level of culture" is, for it differs in every West European country), why not begin achieving the prerequisites for that definite level of culture in a revolutionary way, and then, with workers' and peasants' government and the Soviet system, proceed to overtake the other nations?" ("Selected Works of Lenin," Vol 4, p 691)

Under the leadership of the CCP, through hard struggle for several decades, the Chinese people overthrew at last the three big mountains on their backs and founded the state power of the people's democratic dictatorship led by the working class. Under these circumstances, why should we let the capitalist system which squeezes the masses of working people develop in China? Is it not turning back the wheel of history? Can the masses of the Chinese working people agree with this practice of turning back the wheel of history? Second, with the victory of the new democratic revolution, the comprador class was toppled but the national bourgeoisie was preserved. Can the national capital with its every weakness shoulder the historical task to develop China's national economy? More than 100 years have elapsed since the opium war. During this long period of time, what did the national bourgeoisie develop in the national economy? They ran only cotton yarn mills, flour mills and other sectors of light industry; regarding heavy industry, they could only do repair trade, and the manufacture of complete sets of equipment was out of the question. Their economic strength was pitifully weak. For instance, when joint state-private ownership was realized among all trades and professions in 1956, the result of checking up of assets showed that the national capital throughout the country was only 2.1 billion yuan. This sum of capital was equal to that invested in "the Anshan Iron and Steel Company." The whole national capital could only afford an "Anshan Steel and Iron Company." With what strength could they develop other trades and professions? Since we have established the state power under the people's democratic dictatorship and the state-owned economy under the system of ownership by the whole people on the basis of confiscating the bureaucrat capital of the Kuomintang, then will letting capitalism develop on a large scale be justified in theory or will it work in practice?

3) Some people argue that the new democratic economy existed in China for too short a time. Beginning in 1949, it was only for 7 years. In fact, the new democratic economy consisting of the publicly-owned economy, the cooperative economy, the individual economy and the privately-owned economy was long practiced in the Soviet areas during the agrarian revolution and in the anti-Japanese base areas during the anti-Japanese war, though the scope of the publicly-owned economy was not big at that time. Therefore, the argument that the new democratic economy existed for only 7 years in China does not tally with the facts. According to the "General Line for Transition Period" issued in 1953, the set timetable was 15 years for transforming agriculture, handicraft industry and commerce. Calculated on the basis of 15 years, the time needed to complete the three big transformations and of socialism would have been postponed until 1968. That is to say, beginning with the founding of the PRC to the completion of the three big transformations, it was to have taken 20 years according to the plan. But, in reality, the accomplishment of the three big transformations only took about 4 years. If the pace was not too hasty, if the enterprises with national capital had been allowed to continue to provide the state-run commerce with an ever-increasing variety of commodities with distinctive features for a considerable period of time in the form of state capitalist and if the state placed orders with private enterprises for processing materials or supplying manufactured goods, all this would not have harmed the leadership of the state-owned economy and the socialist construction. Judging from a certain angle, this argument is not wrong. But making use of this formulation to advocate the slogans of "long live new democracy!" and even "long live capitalism!" will be a serious matter. This is because if things are allowed to develop in accordance with this formulation, then the secondary will supersede

the primary and capitalism or state capitalism will become the main body of the national economy, thus the socialist road the Chinese people are taking will be changed. How could this be acceptable to the masses of working people? We admit that the socialist transformation of capitalist industry and commerce was a bit too hasty and was carried out rather roughly. We did not make good use of the personnel of the privately-operated enterprises who were technically skilled and had managerial experience, and we did engage in excessively cutting down, merging, reorganizing and integrating of enterprises. As a result, only a few brand-name products which had their distinctive features and were welcome by the consumers were preserved and a few service and repair networks and centers were retained, thus bringing inconvenience to consumers. However, the party's policies concerning the uniting, educating and remolding of the national bourgeoisie and the socialist transformation of capitalist industry and commerce through the multiforms of state capitalism must be affirmed.

IV. Strive Hard for the Improvement and Consolidation of China's Socialist System

Ours is a socialist country. Viewed from the fundamental characteristics of the socialist economic system, it qualifies as a socialist country. From the angle of the level of development of the socialist economy, ours is in a developing state or rather in an elementary stage. Why is it so? First, before the founding of the PRC, China was a semifeudal and semicolonial country. China's present socialist society emerged from the womb of semifeudal and semicolonial society in which capitalism was undeveloped. After the founding of the PRC, although great achievements were made in China's national economy, a relatively independent and integrated industrial system and national economic system were formed, no fundamental changes have taken place in the level of development of social economy, science and culture, and the influences of the small producers' ways of business, force of habit and feudal traditions are still playing an obstructive role in the development of the socialist economy. Second, after 1949, China achieved initial results both in reviving the national economy and in the first 5-year plan. (Achievements that could not be belittled were also made during 1962-1966 readjustment.) But since 1957, the "leftist" guiding ideology has repeatedly played an obstructive and destructive role in various fields, particularly in the socialist production and socialist construction. The 3 years of the great leap forward and the 10 catastrophic years greatly sabotaged the material resources and finances of the state and people. Besides, the waste caused by the mismanagement of enterprises was fairly amazing. This sabotage and waste caused our national economy to develop rather sporadically, and the superiority of our socialist system could hardly be brought into full play. The "leftist" guiding ideology and backward business management were not the inevitability of the socialist economic system itself but the opposite of the socialist economic system. To subjectively attribute the sabotage and waste caused by the "leftist" guiding ideology and backward ways of business management to the socialist economic system itself or even use this sabotage and waste to negate the existence of our socialist economy is obviously wrong and runs counter to objective facts.

To help our socialist economic system enter the developed stage from the elementary one, the following work must be done:

1) China's socialist system is in an elementary stage and is undergoing the process from imperfect to perfect, and this process cannot be accomplished within 3 or 5 years. This requires us to the socialist system, to try our best to overcome both the "leftist" and rightist guiding ideologies which sabotage the socialist economy, and reform the institutions and ways and means that hamper the development of the productive forces (such as the practices of eating from the same big rice pot and holding iron rice bowls) which are detrimental to improving the standard of living of the people (as the neglect of the second category production). Only when we unremittingly persist in doing things this way can the great superiority of socialism be manifested with each passing day.

2) It is necessary to develop in every possible way China's social productive forces and build a strong socialist material base. This is the only out to solve China's domestic principal contradiction after the basic completion of the socialist transformation (the contradiction between the people's evergrowing demands and the backward social production). Developing China's social productive forces must be carried out in the light of reality and in conformity with economic and natural laws, within the limits of our resources, step by step, after due deliberation and with emphasis on practical results, so that every capital construction unit can form new productive forces on schedule with the required quality and quantity. To develop productive forces, we must not merely "extensively" enlarge the scale of production but also "intensively" enlarge reproduction. Marx said: "The enlargement of places for production means extensive enlargement while the improvement of the efficiency of the means of production means intensive enlargement." ("Das Kapital," Vol 2, p 192) According to our practice, the so-called "intension" means improving the production efficiency of existing enterprises and the tapping, renovating and transforming the existing enterprises. Only when we integrate "extension" with "intension," can we develop our social productive forces while economizing in this effort.

3) The aim of socialist production is to satisfy the ever-growing material and cultural demands of society and the people. So long as satisfying of the ever-growing material and cultural demands of society and the people is carried out, socialist ownership of the means of production can manifest its nature and the socialist system can demonstrate its superiority. For a number of years in the past, under the dominance of "leftist" ideology, efforts to improve the people's livelihood and satisfy the people's demands were neglected. Also during this time, capital construction prevailed over production, while the first category of capital construction and production overwhelmed the second cateogry of capital construction and production. In this way, any improvements in the people's livelihood was of course hard to realize and the satisfying the people's demands was out of the question. In these circumstances, the phenomenon of "production for production's sake" inevitably occurred. The first category was divorced from the second category and from the demands of the people's livelihood, carried out production for simply the development of its own category, and even carried out self-circulation within each category. In this way, the aim of socialist production could not be realized in the best way. Does the aim of socialist production not satisfy the ever-growing material and cultural demand of the society and people but satisfy the self-circulation within the various sectors of the first category? Of course, the importance of the first category brooks no doubts. Without steel and coal of fine quality and abundant quantity, the petrochemical industry and machine-building and other departments, the various second cateogry departments will hardly develop,

hence the demands of society and the people cannot be satisfied. Therefore, we must not negate the importance of the first category because of opposing the wrong of "production for production's sake." With the proportionate and planned integration of production of the first category and that of the second category, the aim of socialist production can readily be seen by the people, thus enabling the people to understand more clearly the superiority of the socialist system and winning greater support from the broad masses of people.

4) It is necessary to raise the enthusiasm of the working people for production by material encouragement while ideologically raising the socialist consciousness of the masses of working people. That is to say, the people are expected to understand that if they deviate from the interests of the whole, personal interests cannot be guaranteed; if they deviate from the long-term interests, we will cease to be able to meet the immediate interests. In the matter of distribution of consumer goods, it is necessary to gradually implement the socialist principle of to each according to his work which takes labor as the only yardstick. If egalitarianism is allowed to continue, it is inconceivable to hope that socialist production will develop by a large stride.

5) The production responsibility systems should be introduced both in socialist industry and agriculture. Of course, there are fundamental differences between the industrial production responsibility systems and the agricultural production responsibility system. The implementation of production responsibility is conducive to carrying out of labor discipline and the realization of scientific operating rules and guarantees product quality. In the process of implementing the eight-character policy of readjustment, restructuring, consolidation and improvement, the introduction of production responsibility system and the carrying out of strict labor discipline and technical operating rules will become the important curricula of restructuring and consolidating.

6) To do a proper job in the socialist economy, it is necessary not only to raise the socialist consciousness of the laboring masses ideologically but also raise the technical level of the technical personnel and those working in science and technology. This is a necessary condition for improving the productive forces of enterprises. The more modern the country is, the more it needs personnel with high technical levels. Improving the scientific and technical levels and training the scientific and personnel in new techniques are not things that can be accomplished in a single day. We must acknowledge that China's current levels of science and technology are backward when compared with those of the developed countries in the West. This does not mean that we should become discouraged. It requires that we continue to exert ourselves and fight to improve China's scientific and technical levels, raise our social productive forces and increase our labor productivity.

The Chinese people are a people with high aspirations. The CCP is a long-tested and great party. Without the CCP, there would be no new China. This is hard fact.

It was no other than the CCP that led the Chinese people in overthrowing the three big mountains and smashing the feudal and comprador relations of production; it was none other than the CCP that smashed the "gang of four" and corrected the "leftist" guiding ideology existing within the party. It is unimaginable for China's new democratic revolution, its socialist revolution and socialist construction will break away from the CCP. "Only socialism can save China." Taking the socialist road under the leadership of the CCP is the basis for the people's democratic dictatorship and our guide is Marxism-Leninism-Mao Zedong Thought. We can advance steadily and should continue to sum up experiences. Under the leadership of the CCP, the Chinese people will implement the eight-character policy of readjustment, restructuring, consolidation and improvement which will lead to perfecting the socialist system while simultaneously correcting any shortcomings in it. This will lead to the development of material production and the enhamcement of spiritual civilization. The Chinese people will surely be able to continue to bring the superiority of the socialist system in to play in accordance to the demands of objective economic and natural laws.

SOCIALIST TRANSFORMATION DISCUSSED BY 'JINGJI YANJIU'

HK250826 Beijing JINGJI YANJIU [ECONOMIC RESEARCH] in Chinese No 7, 20 Jul 81 pp 25-33

[Article by Wu Chengming [0702 2110 2494] of the Economics Research Institute of the Chinese Academy of Sciences: "The Socialist Transformation of Capitalist Industry and Commerce Is a Victory of Marxism in China"]

[Text] "The resolution on certain questions in the history of our party since the founding of the People's Republic of China adopted at the 6th Plenary Session of the 11th CCP Central Committee has profoundly summed up both positive and negative historical experiences of socialist revolution and construction in the 32 years since the founding of the People's Republic. This is of utmost significance in guiding our work in the socialist modernization and construction and various fields in the days to come. Now I would like to discuss my understanding of the problems concerning the socialist transformation of capitalist industry and commerce in our country which has come from my study of the "resolution."

The socialist transformation of capitalist industry and commerce in our country is the materialization of the strategic thinking of Marx, Engels and Lenin concerning the proletariat overthrowing the bourgeoisie. It is the embodiment of Lenin's policy of enforcing state capitalism under the dictatorship of the proletariat, and substantiates Marxist theories concerning the transition period by adopting the guideline of uniting, educating and transforming bourgeois elements while transforming the production relations. The accomplishing of this transformation is the victory of Marxism in China.

The Level of Capitalist Development in Old China

Socialism is the developed negation of capitalism. It is quite obvious that socialist revolution and the socialist transformation of the national economy will never happen in a country without a fairly developed capitalist economy and a relatively powerful proletariat.

Old China was a semicolonial semifeudal country, where capitalist production was just like a small isolated island emerging from an ocean of individual agriculture and individual handicrafts industry. Yet, it was still developing. Below is a table based on my preliminary calculations.

Table 1. The Level of Capitalist Development in Old China

Year	The percentage proportion of modern industry to the total output value of industry and agriculture	The percentage proportion of modern industry and workshop handicrafts industry to the total output value of industry and agriculture	The percentage proportion of modern communications and transportation to the total revenue of communications and transportation industry
1920	4.9	10.8	45.6
1936	10.8	20.5	51.0
1949	17.0	23.1	

Note: Modern industry denotes those enterprises employing machines and mechanical power in production, which includes mining. The modern communications and transportation industry includes railway, highway, shipping, aviation, telecommunications, and so forth.

Until the eve of the liberation, capitalist production still only amounted to around 20 percent of the total output value of industry and agriculture. But, it controlled the banking system, the trunk lines of water and land transportation, the import-export trade and the markets in large cities throughout the country. Capitalism had dominated the lifeline of the national economy. And in the 1920's, the Chinese proletariat arrived on the political arena and took up the lofty mission of leading the Chinese revolution.

In old China, although the capitalist production relations were fairly developed, the basis of the productive forces still remained quite weak. With liberation in 1949, modern production equipment in the whole country only amounted to 12.8 billion yuan. In other words, the fixed assets amounted to only 12.8 billion yuan in 100 years after the rise of modern industry in old China. Today, in our country, the industrial fixed assets exceed 400 billion yuan, and grow by tens of billions every year. By these facts, we can see how meager a heritage old China had left to us. However, our socialist construction and the modernization of the national economy had to start from this weak basis, which was determined by the history.

According to the principles of Marxist political economy, socialism must be based on socialized great production; in other words, it highly requires developed productive forces. Yet it is in a country with underdeveloped productive forces that the Chinese revolution was victorious. That brought about a very serious contradiction.

The solution to this contradiction is neither to return to capitalism nor to hesitate and wait, but to rely on Marxism, in particular the transition period theory which Lenin formulated in the light of the conditions in Russia, "a state of the extremely backward petite bourgeoisie (in particular, the peasants)." Integrated with the historical reality in China, it brought about the party's general line for the transition period which was put forth by Comrade Mao Zedong in March 1949 and adopted at the meeting of the Political Bureau of the CCP Central

Committee in June 1953. The general line advocates the "basic realization in a rather long period, the nationwide industrialization and the socialist transformation of agriculture, the handicrafts industry, capitalist industry and commerce." This is a line which develops modern productive forces while simultaneously transforming the relations of production. Industrialization is the material basis for socialist transformation, and the socialist transformation must contribute to the development of the productive forces.

The State Monopoly Capitalism in Our Country

Is it possible for the weak capitalist economy in our country to undergo a socialist transformation?

Although the material basis of the capitalist economy in our country was quite weak, it was very concentrated. Before the war of resistance against Japan, it was mainly centralized under the control of the foreign capital enterprises established in China. The following table shows my preliminary estimations.

Table 2. The Estimation of Industrial Capital in the Whole Country in 1936

		Percentage Proportions of Each Category		
	Investment Value (billion yuan)	Foreign Capital Enterprises	Bureaucrat Capital	National Capital
Industry and mining	4.296	68.0	4.8	27.2
Communications and transportation industries	3.914	89.8	6.0	4.2
Total	8.210	78.4	5.4	16.2

Note: The investment value denotes in principle the next value of assets of enterprises in each category by calculating in today's currency.

Such a situation did not change substantially until the end of the war of resistance against Japan. The Japanese investment which made up 87 percent of total foreign investment, and the properties of the German and Italian fascists in China were then transferred into the hands of the bureaucrat-capitalist class. All the above, together with those assets gobbled up during wartime by the enterprises run by the Kuomintang bureaucrats, formed the bureaucrat capital which amounted to around 80 percent of the total fixed assets of the industrial, mining, communications and transportation enterprises, thus became a genuine state monopoly capitalism.

Such a state monopoly capitalism, in its nature, had already become socialized great production. Its major part (including the former foreign investment portion) had reached a fairly high level of production technology. Lenin said, "The state monopoly capitalism is the most complete material preparation for socialism. It is the beginning toward socialism, a step on the historical staircase from which one can climb up to another step called socialism. There is no middle step in between." ("Selected Works of Lenin," "What Is the Way Out to Imminent Disaster?," Vol 3, p 164) Obviously it would be a monstrous absurdity if the proletariat would be the least hesitant in transforming this capitalist part of economy into a socialist one after they had seized the political power.

Having confiscated all bureaucrat capital, the party and government built up a powerful state-owned economy through democratic reform and production restructuring. So 80 percent of the socialist transformation of the capitalist economy was accomplished. The production in the state-run industries rose from 3.73 billion yuan in 1949 to 15.12 billion yuan in 1952, a three-fold increase in 3 years. This fact proved that we have been correct in liberating the productive forces.

State Capitalism in Our Country

To transform the national capitalist economy step by step through the stage of state capitalism was the policy put forth by Lenin after the October revolution. though it was not carried out then. Lenin pointed out that the development of capitalism is inevitable when hundreds of thousands of small-scale production enterprises still exist. "Since we still cannot realize the direct transition from small-scale production to socialism," we have no alternative but "to bring such a development onto the track of state capitalism," and make use of state capitalism "as the intermediary link between small production and socialism, as means, a path and a method of increasing the productive forces." (ibid, "On the Grain Tax," Vol 4, pp 519, 525)

Lenin's initial idea was actually materialized in our country. Moreover, the nature of state capitalism under the dictatorship of the proletariat was further ascertained in the practice. While the form of state capitalism at different levels were created and regularity of their development was revealed.

The first step is to turn the laissez-faire capitalism which was blindly developed and operated in an anarchical way into the capitalism which would be under the control of the state's administration, the leadership of the state-owned economy and the supervision of the worker masses; or in Lenin's words, the state capitalism which "we can restrict and regulate in terms of its limits of activities." ("Collected Works of Lenin," "The 11th Congress of the Russian Communist Party (Bolshevik). Political Report of the Central Committee of the Russian Communist Party (Bolshevik)," Vol 33, p 244) This task was completed in 1952. During that period, privately operated industry grew at a rate of 10,000 a year, and their total output value increased by 54.2 percent in 3 years. The following table shows detailed figures.

Table 3. The Development of Privately Operated Industry and Commerce in 1949-1952

	1949	1950	1951	1952
Privately operated industry:				
Number of households (10,000)	12.30	13.30	14.76	14.96
Workers and staff (10,000)	164.38	181.59	202.28	205.66
Total output value (100 million)	68.28	72.78	101.18	105.26
Privately operated commerce:				
Number of households (10,000)		402	450	430
staff (10,000)		662	740	676
Retail sales value (100 million)		101.0	132.8	121.9

Since 1953, capitalist industry and commerce began to be merged in a planned way into various forms of state capitalism.

State capitalism in our country was an integration of and a cooperation between the socialist economy and the capitalist economy in varying degrees under the leadership of the socialist economy. The differences in degrees lead to it being divided into primary, advanced and superior classes.

The primary form of state capitalism may be represented by the privately operated industry which received processing orders from the state-owned economy. It was the integration of and cooperation between the socialist and capitalist economy outside enterprises or in the course of circulation. It enabled the production of privately-run enterprises to merge into the track of state plan, brought the productive forces into play, and expanded the socialization of production. The development of orders of processing is shown in table 4.

Table 4. The Development of Processing Orders in 1949-1955 (monetary unit: 100 million yuan)

	1949	1950	1951	1952	1953	1954	1955
1)	68.28	72.78	101.18	105.26	131.09	103.41	72.66
2)	8.11	20.98	43.21	58.98	81.07	81.21	59.35
3)	11.88	28.83	42.71	56.04	61.84	78.53	81.69

1) stands for the total output value of privately-run enterprises in the whole country; 2) stands for the portion of processing orders in the total output value; 3) stands for the percentage of 2) to 1).

Note: The output value of processing includes the portions of purchasing, state monopoly for purchase and marketing.

After 1954, as many privately-run enterprises were transformed into joint state-private enterprises, the output value of processing orders did not rise a lot or even decrease. With the portion due to the transformation from privately operated enterprises to joint state-private enterprises reduced, the output value of processing orders increased in 1954 by 19.3 percent over 1953, whereas in 1955 it increased by only 1 percent over 1954.

The advanced form of the state capitalism is joint state-private ownership, which is cooperation between the socialist economy and the capitalist economy components inside enterprises in the course of production. The prodiction relations underwent a fundamental change, since the means of production which had been privately owned before were now under joint state and private ownership, the socialist component took the dominant position and the production and operation of enterprises were included in the state plan. Therefore, the joint state-private ownership was the decisive step in the whole socialist transformation.

The state-private ownership enabled production in enterprises to be further socialized, and greatly liberated the productive forces. This can be seen in the yearly growing of the fixed output value and the gradual rising of workers' productivity shown in table 5. Until 1955, the productivity of workers in joint state-privately owned industry was about double of that in privately operated industry. The new ownership also proved to be very effective in saving raw materials and lowering costs. In the years of 1950-1955, the state-privately owned industry throughout the country gained a total profit of 1.273 billion yuan, thus making improvement of equipment and the expansion of reproduction possible.

Table 5. The Development of State-Privately Owned Industry in 1949-1955

	1949	1950	1951	1952	1953	1954	1955
1)	193	294	706	997	1,036	1,746	3,193
2)	10.54	13.09	16.63	24.78	27.01	53.33	78.49
3)	1.30	2.40	3.28	5.37	6.93	14.00	18.75
4)	2.20	4.14	8.06	13.67	20.13	50.86	71.88
5)		2.58	5.44	10.66	17.54	25.26	52.34
6)		17.3	31.4	32.2	28.3	25.5	2.9
7)		4,257	6,553	9,297	10,880	13,401	13,358

1) The number of households
2) The number of workers and staff (10,000 persons)
3) Capital value (100 million yuan)
4) Total output value (100 million yuan)
5) Fixed output value (100 million yuan)
6) The increase in fixed output value over the previous year's total output value (percent)
7) Output value per worker (yuan)

Note: Joint state-privately owned enterprises were usually formed with several privately-run enterprises, therefore this table cannot be compared with table 3. Fixed output value is equal to this year's total output value minus the output value made by enterprises which had been transformed into joint ownership that year.

In the high tide of the socialist transformation in 1956, the conversion of all capitalist industry and commerce into joint state-private ownership in the whole trade was completed in its entirety, and the fixed interest system was carried out.

The enforcement of the whole-trade joint state-private ownership combined with the system of fixed interest was the superior form of state capitalism in our country. Under such a system, all the means of production for enterprises were distributed in a unified way, private investments would no longer play a role as functional capital, and capitalists would no longer engage in the operation and administration of enterprises in the power of capital proprietor but as a staff member named by the state. The enterprises would become wholly socialist as soon as fixed interests were terminated.

The Problem About the Speed of Transformation

According to the party's general line for the transition period, socialist transformation would be basically realized in quite a long period which would last for 15 years (from 1953 onward) or even longer as depicted in the tentative plan. However, a problem rose--since socialist transformation was basically completed in 3 years or more owing to the transformation high tide in 1956--whether the transformation had been enforced too fast and whether such a "hightide," as a form of the transformation, was rational.

As gifted at the very beginning with the regularity that developing things evolve from elementary to advanced stage and from quantitative to qualitative change, the state capitalist structure in our country possessed a self-accelerating mechanism. But, such a mechanism could not be initiated spontaneously; it would work only when people were knowledgeable about objective economic laws, and dealt with and steadily overcame contradictions. The transition from processing orders to the joint state-private ownership had undergone such a process.

Such a transition was carried out in household after household according to annual plans. In 1954, 793 enterprises were transformed; in 1955, 1,091 enterprises; both were not on a large scale. But all of those enterprises were formerly the larger ones in privately operated industry. Therefore, in 1955 the output value of joint state-privately owned industry had already amounted to 49.7 percent of the total output value of both state-privately owned and private enterprises, and the capital value of the joint state-private enterprises had even made up 69.8 percent of the total capital value of both kinds of enterprises. In other words, just before the hightide, half of the enterprises in terms of the productive forces, and 70 percent of them in terms of ownership, had already been basically transformed. What had been left to be solved in the hightide was the problem concerning the remaining half and 30 percent.

The utmost difficulty we faced then was the contradiction between the joint state-private enterprises and the private ones. At that time, if a plant was transformed from private ownership into joint state-private ownership, its output value in the first year after the transformation would on average rise by 30 percent over that made before the transformation, thus creating problems for the untransformed small plants in the same trade in distribution of production order, supply of raw materials and marketing. In some cases, capitlaists even fell into such dire straits that they were unable to pay workers' wages. This kind of contradiction was even more acute in commercial sectors. So, in order to eliminate this contradiction, the central authorities put forth in the latter half of 1954 the policy of overall consideration and all-round arrangement, and in the first half of 1955 the policy of "eating grapes" (that is to say, state-run departments undertake the whole production operation of those privately run trades which suited market demands one trade after another.) Then in the latter half of 1955 the whole trade joint state-private ownership in industry and commerce was trial-enforced in Beijing and Shanghai. Therefore, the whole trade joint state-private ownership was not a creation of the mass movement in the hightide but the comprehensive popularization of the above-mentioned experiences.

For the above reason, the transformation of whole-trade joint state-private ownership speedily completed in the hightide actually resulted in fairly good results in terms of direct economic results. The output value of the joint state-privately operated industry increased by 30 percent over 1955; the sales value of joint state-privately owned shops, cooperative shops and cooperative groups increased by 15 percent over 1955. Of course, this was partly due to the consolidation of the transformation results and vigorous help from the state.

The socialist transformation of capitalist industry and commerce was not carried out in isolation, it was closely related to the socialist transformation of individual economy, in particular that of agriculture. Lenin looked upon state capitalism as the link joining small production and socialism in consideration of the greater difficulty of transforming the agricultural individual economy which is basically carried out by manual labor. The collectivization of agriculture was completed in the Soviet Union 10 years or more after than the nationalization of industry. The case in our country was quite the contrary. In 1953, there were 15,000 agricultural production cooperatives throughout the country, less than 1 percent of the total agricultural households joined these cooperatives. In the summer of 1955, the number of cooperatives increased to more than 430,000. In the latter half of that year, the socialist hightide in rural areas was unfold, and the collectivization was realized in quite a few provinces and cities in the same year. In the summer of 1956, the agricultural households which joined cooperatives amounted to 91.9 percent of the total agrarian households in the whole country, and the collectivization of agriculture was basically completed.

As the vast majority of our country's population spread over rural areas, cities had to strive to keep pace with rural areas where socialist transformation had been completed. A socialist country, with the transformation of industry and commerce in cities accomplished, can still retain some portion of private agriculture in rural areas. That is acceptable and also usual in the history. However, if capitalist industry and commerce are still retained in cities while the transformation of agriculture has already been completed, that can hardly be imaginable. The hightide of whole-trade joint state-private ownership in 1956 was in fact pushed ahead by the socialist high tide in rural areas. In those days, whenever news came from rural areas, not only the departments and comrades who were in charge of the transformation of industry and commerce felt the heavy burden, but also hundreds of thousands of private industrialists and businessmen felt they were on tenterhooks. In the spring of 1956, starting from Beijing, capitalist industrialists and businessmen, one after another, began to make application for transforming their enterprises into joint state-private ownership. Such a development is quite understandable.

The high tide of whole-trade joint state-private ownership was pushed ahead in the form of the mass movement. Nevertheless, at that time, whether party committees or united front departments at different levels from central down to the local paid close attention to the enforcement of the transformation. While at the same, all state-run industry and commerce departments, industrial and commercial administrative departments and labor unions, industry and commerce federations, China Democratic National Construction Association at all levels, and so forth, all of them worked conscientiously and spared no effort in carrying out the transformation. This is entirely different from the haphazardness and mess which we witnessed during the later "great leap forward" and the 10-year upheaval.

In spite of this, we will have to admit that the speed of the transformation in 1956 was a little bit too fast, and thus brought about some prematurity in the whole-trade joint state-private ownership and some shortcomings in our work.

First of all, the extent of joint state-private ownership was too wide. In 1954, 96.4 percent of the privately run industrial enterprises belonged to workshop handicrafts industry. As their productive level remained relatively low, in effect, they were not suited for extensive transformation into joint ownership. While at the same time, 96.4 percent of the privately run commerce were small shopkeepers and peddlers, 1.6 percent employed fewer than 2 persosn, all of them were only suitable for transforming into cooperatives or maintaining private ownership. All these circumstances were certainly considered then, and many forms were utilized in the transformation. The results can be seen in table 6 and table 7. But in general, the extent of joint state-private ownership was still too wide, the areas designated for collective economy and private ownership seemed a little bit too small. On the other hand, there were more than 48,200 handicrafts households which joined the joint state-private ownership on their own during this period. They were requested to resume private ownership in the readjustment later, but the policy was not thoroughly carried out.

Table 6. The Transformation of Privately Owned Industry in 1956

	Number of households (1,000)	Number of staff and workers (1,000)	Total output value (million yuan)
The results in 1955 after the first transformation	88.80	1,310	7.266
1. Those transformed into joint state-private ownership	67.23	1,075	6,545
2. Those shifted into local state-run enterprises	1.00	23	98
3. Those designated for the transformation of handicrafts industry	15.60	117	299
4. Those transformed into joint state-private ownership or others	7.10	81	295
5. Those retaining private ownership	0.87	14	29

Table 7. The Transformation of Privately Owned Commerce in 1956

	Number of Households (1,000)	Number of staff and workers (1,000)	Capital Value (million yuan)
The results in 1955 after the first transformation	2,423	3,138	841
1. Those transformed into state-run enterprises and supply and marketing cooperatives	147	224	--
2. Those transformed into joint state-private ownership	401	877	601
3. Those transformed into cooperatives	1,443	1,723	184
4. Those retaining private ownership	432	494	56

Footnote: There were 757,000 or more households in the privately operated catering trade, 327,000 or more households in the privately operated service trades. They were transformed in a form generally like that of the privately owned commerce.

Second, the economic restructuring after joint ownership transformation was somewhat overdone. As economic organizations must conform to the level of productive forces and the market demand, the central authorities put forth the restructuring principles of popularizing coordination between specialized departments and "carry out readjustment in a number of enterprises while preserving the status quo in most of them" as soon as the whole-trade joint ownership transformation was completed. However, because of the impact of the high tide, these principles were not completely carried out. Although specialized companies as leading mechanism were set up, too much emphasis was placed on "changing" in the readjustment. Statistics compiled in June 1957 shows that among those plants which were transformed into joint ownership during the high tide, about half were merged, and only one-third adopted integrated administration. And again, unified accounting was enforced in more than half of the latter. The practice of eating in the same canteen was unfavorable to giving play to the enthusiasm of small plants.

However, it is the later "great leap forward" that worsened all those weaknesses. During the "great leap forward," the barrier between joint state-private ownership and state ownership and that between joint state-private ownership and collective economy were broken down. As policies were carried out without substantially understanding, enterprises were either cut down, or merged or transformed or integrated which all culminated into a mess. Thus, what followed was a lot of problems.

Because too many enterprises were merged and integrated, aiming at the expansion of scale and the seeking of comprehensiveness, production was made unitary, and the variety of products reduced. As points in the commercial network were insufficient, the circulation of commodities was blocked. Many small industrial and commercial households which formerly were independently run and helped to the society's economy, were losing their positive functions. This problem was not solved until 1980 when the collective economy in towns had been resumed and fostered, and due attention had again been paid to the ownership of enterprises under the collective ownership system.

Because of this transformation, a great number of small proprietors, small handicraftsmen, small peddlers were involved in changes concerning the joint state-private ownership or regarded as "representatives of private party" and the equivalent to the bourgeoisie. This doing confused the class barrier and harmed their enthusiasm in production. Again, this problem was not solved until 1980 when the instruction was issued by the central authorities to correct the mistake.

The joint state-private ownership was originally designed to fit to the fairly backward productive forces of the capitalist economy in our country. The reason was that we could not directly transit to socialism from such a basis. However, when the whole-trade joint state-private ownership had been enforced less than 2 years, the system of coordination between specialized departments had just been set up, and the joint ownership had not yet been able to fully work, the "great leap forward" started and threw everything into disarray. We could have envisaged a better situation if the system had been preserved until 1966 when the fixed interest was terminated.

On the Redemption Policy

More than 100 years ago, Marx and Engels pointed out in "The Communist Manifesto" that after having seized that political power of a state, the proletariat "will make use of their own political rule to seize all the capital of the bourgeoisie step by step; to centralize all the tools of production under the control of the state, that is, the proletariat will organize to form the ruling class and to raise the total volume of the productive forces as soon as possible." ("Selected Works of Marx and Engels," Vol 1, p 272) That is exactly what we did during socialist transformation.

"Deprive those who deprive," is the basic principle of socialist revolution in the economic field. But in what way this principle is to be carried out will depend on the historical conditions. In "The Fundamental Principles of Communism," Engels proposed a number of possible ways including confiscation and redemption. Marx also pointed out that to accomplish this task by redemption will be "the cheapest way" for the proletariat. (Ibid, "The Agrarian Problems in France and Germany," Vol 4, p 315) They did not discuss under what conditions the redemption should be carried out, because they had no such experience in this regard. "To attempt to answer in advance" would only have "resulted in a fantasy." (Ibid, "On the Housing Problem," Vol 2, p 545)

After the October revolution in Russia, Lenin put forth the policy of combining redemption with the state capitalism. He advocated carrying out the policy of redemption for those civilized capitalists who would accept state capitalism, and resolutely punish those uncivilized capitalists who were doing evil. Nevertheless, this plan of Lenin was never properly enforced.

Lenin's idea was implemented in our country, and various forms of redemption were also derived in actual practice. The development of the forms of redemption reflected the change of the production relations of the state capitalism in different stages, and also the fact that the production of surplus value was more and more restricted. On the other hand, as a system, redemption will in turn have impact on the development of the state capitalism and on the transformation of the production relations and that of bourgeois elements.

Redemption is not a transaction, not simply purchasing of the means of production from capitalists, but a firm class policy of the proletariat, or in other words, a strategic guideline for the socialist revolution. It is different from the compensation offered when nationalization is enforced in a country at present. The crux of redemption in our country is that the proletariat, while working and producing for the people's needs, offer as well as a share in the profits with capitalists.

The redemption in our country can be generally divided into two stages: Before and after the enforcement of the whole-trade joint state-private ownership in 1956. In the first stage, we took the measure of profit distribution, a typical example was the method of "four horses sharing food" adopted in 1953, in which the share to capitalists could have amounted to 25 percent of total profit. In the second stage, redemption was carried out in the way of fixed interest, that is, issuing fixed dividend in accordance with the amount of private shares in joint state-private enterprises. Generally, the annual interest was 5 percent, and the fixed interest continued to be issued for 10 years.

The content of the redemption in the stage of interest distribution is shown in table 8. There is one point I should make clear about the table, those among the privately run enterprises whose accounts could be examined (the so-called account checking households) were only a few, therefore, the items given in the table are only rough appraisals based on sampling survey. Enterprises suffering from losses are not included in the table because they were not subject to redemption under the system of profit distribution. The item of proprietor's income includes both capitalists' income from profit distribution and the total income of the representatives of capitalists and some small proprietors. That is because of the unsoundness of the accounting system in many enterprises which made it difficult to distinguish one part from another. Anyway, that does not cause a great discrepancy in terms of percentage. Based on this percentage distribution, the income of proprietors in the 6 years was roughly 1.4 billion yuan.

Table 8. The Appraisal of Profit Distribution for Privately Run Enterprises in 1950-1955

Total value of profit (100 million yuan)		Profit Distribution in Percentage			
		Income Tax	Income of Proprietors	Other Distributed Items	Undistributed Parts
1950	8.31	26.53	31.54	14.42	27.51
1951	16.41	36.50	24.11	14.32	25.07
1952	7.30	35.28	28.99	16.17	19.56
1953	16.98	39.87	16.48	20.78	22.87
1954	7.42	38.01	19.66	19.06	23.27
1955	4.71	35.27	21.21	19.82	23.70
Total	61.63	36.02	22.87	17.34	23.77

Footnote: Privately run industry, commerce, catering industry and service trades are included.

During these 6 years, dividend and bonuses distributed to private shareholders of joint state-private enterprises amounted to about 100 million yuan.

The enforcement of fixed-interest system after the whole-trade joint state-private ownership is shown in table 9. The fixed interest rate was not a uniform 5 percent for all trades. But, it is still proper if we calculate based on the total value of private shares given in table 9, and in a rate of 5 percent and in a term of 10 years. Appraised in that way, the total value of fixed interest turns out to be 1.15 billion yuan.

Table 9. The Issuance of Fixed Interests in Joint State-Private Enterprises in the First Half of 1956.

	Number of households adopting fixed-interest system	Value of private shares (100 million)	Percentage of private shares to the total capital	Due dividend for the first half of 1956 (10,000 yuan)
Industry	43,687	17.83	77.27	4,455.5
Commerce	97,235	3.53	15.29	881.0
Catering industry	14,408	0.18	0.80	44.9
Service trades	12,741	0.36	1.57	91.0
Transportation	22,828	0.75	3.24	174.3
Banking	3	0.42	1.83	112.9
Total	190,902	23.07	100.00	5,757.6

The grand total of the three big items [the three items include the income of the proprietors of private enterprises in 1950-1955, the dividend and bonus distributed to the private shareholders of joint state-private enterprises for the same period and the total value of fixed interests issued to the private shareholders in the 10 years after the whole-trade joint state-private ownership was realized] is roughly equal to the original capital of the bourgeoisie.

Apart from these, the redemption from capitalists also included the salaries which enterprises paid to capitalists at and which were higher than the salary level for the same posts in state-run enterprises. The high salaries of all these capitalists were maintained after the transformation of joint state-private ownership.

At large, our policy of redemption was quite reasonable, which satisfied the bourgeoisie and played an important role in pushing ahead with the transformation. During the 10-year turbulence, the fixed interest due to industrialists and businessmen was withheld and their high salaries were reduced. In 1979, the central authorities decided to pay back all fixed interest and salaries that had been withheld, and resume the high salaries which had been lowered, return all deposits which had been confiscated and frozen. Indeed this is "to carry out the redemption through to the end."

The Transformation of Bourgeois Elements

The socialist transformation of capitalist industry and commerce in our country included the transformation of bourgeois elements, which aimed at helping them to change themselves from being exploiters by gradually becoming laborers in the socialist society.

Based on the Marxist dialectic principle concerning social being and consciousness, Comrade Mao Zedong always advocated that everyone needs to be transformed in order to further the revolutionary cause and that men can undergo transformation. Back in 1977, he pointed out in "On Practice" that the struggle of the proletariat and the revolutionary people to transform the world includes "the transformation of the objective world as well as that of their own subjective world" and "the so-called objective world to be transformed includes all those who initially reject transformation." ("Selected Works of Mao Zedong," Vol 1, People's Publishing House, 1966 horizontal setting edition (similarly hereinafter), pp 272-273) After the victory of the democratic revolution, he emphatically put forth again, in his articles such as "On the People's Democratic Dictatorship," "Problems Concerning the Correct Handling of the Contradictions Among the People" and so on, the problems concerning the transformation of bourgeois elements.

Our country's national bourgeoisie is a class with dual character--they possess a revolutionary character on one hand, and a tendency towards compromise on the other. Their contradiction with the working class is a contradiction within the people. The transformation to them should be processed in a democratic way, that is, the way of criticism and education. The party's policy towards them can be summed up in unity, education and transformation.

The transformation of bourgeois elements was carried out along with the transformation of capitalist enterprises. During the whole with the transformation of enterprises through the state capitalism, capitalists were not excluded but involved in the evolution. In fact, a lot of concrete transformation works were done by themselves. Hence their ideology could be transformed step by step through the transformation of production relations, through production struggle and class struggle. This helped to eliminate obstacles and spur the transformation of the ownership system.

Our country's national bourgeoisie was one of the classes in the old China which were comparatively cultured and possessed more intellectuals. Therefore, the transformation of bourgeois elements, combined with personnel arrangement, was enforced as a task to bring every positive factor into play and make use of their scientific and technological knowledge and operational and administrative experiences. It should be noticed that during the 10-year turbulence, as enterprises were transformed from joint state-private ownership into state ownership, the original personnel allocation was shaken, most of the former industrialists and businessmen were transferred to do manual labor or dismissed, and the learning system, contest and appraisal system, health and welfare system for them were destroyed. Indeed this was a great loss for the transformation cause. These wrong doings have been mended step by step only after the defeat of the gang of four.

In our country, the transformation of bourgeois elements was proposed as a great task of the proletariat to transform the world and abolish classes. When the democratic revolution won the victory throughout the country in 1949, Comrade Mao Zedong already made the transformation of members of the reactionary ruling classes which had just been overthrown by the people a task in thoroughly carrying on the democratic revolution. He also pointed out, "If this job is well done, the major exploiting classes in China, that is, the landlord class and the bureaucrat bourgeoisie or in other words, the monopoly bourgeoisie, will eventually be eliminated." (Ibid, "On the People's Democratic Dictatorship," Vol 4, p 1,414) In 1957, after the socialist transformation of the ownership system had been completed, he said, "It is imperative to digest them. To transform landlords and capitalists into laborers, this is also one of the strategic guidelines. To abolish classes will take a very long time." (Ibid, "Speech At the Meeting of Party Committee Secretaries of Provinces, Cities and Autonomous Regions," Vol 5, p 342) To transform through unity and to abolish classes through digesting exploiters, this is exactly our guiding principle.

The transformation of exploiting class members on such a large scale and such a planned way was a pioneering work in the history. It provided new experiences to the proletariat revolution and the international communist movement, and made contribution in replenishing the Marxist theories concerning the withering away of classes.

Today, the feudalist and capitalist exploiting systems have been abolished in our great country (except the province of Taiwan). The landlord class and the rich peasant class as classes have been eliminated. So did the capitalist class. After 30 years' education and struggle, the great majority of them who have working ability have already been transformed into laborers of the socialist society; and most of the rest are patriots who support the socialism. This is a great victory of Marxism-Leninism-Mao Zedong Thought.

'JINGJI YANJIU' PROBES TIANJIN RETAIL TRADE

HK260135 Beijing JINGJI YANJIU [ECONOMIC RESEARCH] in Chinese No 6, 20 Jun 81 pp 27-33

[Article by Zheng Ning [6774 1337] and Wang Shiquan [3769 1102 0356] of the Economics Research Institute of Tianjin Academy of Social Sciences: "Investigation on Responsibility for One's Own Profits and Losses in Trial Points of Tianjin State Run Retail Trade"]

[Text] During the implementation of the eight-character principle which centers on readjustment, beginning from September 1980, the Tianjin Financial and Trading Commission carried out investigation on the trial points of reforming the system and expanding enterprise autonomy in 24 retail shops of nonstaple food, general merchandise, sweets and cakes. The purpose of having such trial points is to solve the problem of the ownership system and the method of management and administration and to carry out the principle of distribution according to work, to change the phenomenon of "eating out of a big pot," to make enterprises relatively independent commodity operational units, to link the economic interests of enterprises and staff and workers with the management results of enterprises, to bring into full play the initiative of enterprises and staff and workers, to improve management, to enliven circulation, to improve economic effect and better serve production and the people's livelihood.

According to the financial system, trial points are divided into three types: The first one is to change from the system of turning over the profits to the state to the system of state taxation and to be responsible for one's own profits and losses. The number of units which have done so is 10. The second one is to retain the profits. The number of units which have done so is six. The third one is to be responsible for turning over the profits to the state on a trial basis. There are four units which have done so. Four collection ownership units have made the accounting units smaller and improved the way of management so as to bring into play the characteristics of collective ownership. Viewed from the angle of trial points, all units have generally achieved rather good results.

I

There are two different forms of trial points for independent accounting, substitution of tax for profits and responsibility for one's own profits and losses, which are carried out by the state-run retail trade.

The first form is "five taxes and one charge." The units which have implemented this method are Shiyi Jinglu Department Store and Shiyi Jinglu Nonstaple Food Store. They studied and adopted this method on the basis of the principle of retaining profits which was experimented with in 1979 and by referring to the categories of taxes and tax rate which were implemented in the past. The specific tax rate and charge rate are as follows: The industrial and commercial tax accounts for 3 percent of the total sales. In the real estate tax, the (annual) landed estate tax is 0.72 yuan per square meter, and the (annual) house property tax is 1.2 percent of the original value of the house property. The income tax is 40 per mill of the profits. The local additional tax is 15 percent of the income tax. The charge for using the circulating funds is 0.21 per mill.

The income readjustment tax due to the difference in grade is for readjusting the disparity of profit levels and the unevenness of hardship and happiness caused by nonsubjective reasons such as different trades, the scale of shops, the structure of commodities and the location where business is done. The rate for the readjustment tax of these two trial-point stores has been calculated under the prerequisite of retaining the profits. For instance, according to the experience over the years, the Shiyi Jinglu Department Store has defined that the proportion of the profits to be retained is 30 percent, while 70 percent is to be turned over to the state. After deducting the four kinds of taxes and the charge for the use of circulating funds, the balance in the amount turned over to the state is approximately 2.3 percent of the total sales. This is the rate for readjustment tax. The rate for readjustment tax of Shiyi Jinglu Nonstaple Food Store is 0.6 percent.

The second form is "proportional income tax." The units which have implemented this principle are the Tanggu District Jiefang Lu Department Store and the eight shops of the Qiandezhuang Basic-Level Vegetable and Nonstaple Food Store in Hexi District. This form has been defined according to the tax profits remitted to the state by the stores over the years, the amount of funds returned to the stores by the higher authorities and by considering other factors. Different stores have different rates. For instance, after deducting the returned amount, the Qiandezhuang Basic-Level Vegetable and Nonstaple Food Store, based on the average amount of the tax or profits turned over to the state in the past 3 and 1/2 years, defined that 58 percent of the total profits is to be turned over to the state as income tax and that 42 percent is to be retained by the enterprises themselves.

After the method of "substituting tax for profits" has been implemented, the profits after tax will be used as the enterprises' development funds, collective welfare funds and staff and workers' reward funds according to a certain proportion. All this is at the enterprises' disposal. Different units have different proportions of allocation. For instance, the proportional allocation of Shiyi Jinglu Department Store is 50:30:20; that of Shiyi Jinglu Nonstaple Food Store is 35:25:40; that of the Tanggu District Jiefang Lu Department Store is 40:20:40.

During the carrying out of the trial points of being responsible for their own profits and losses, the enterprises have done the following work:

(1) They have expanded enterprise autonomy in the trial point units. According to the stipulated range of use, the enterprises can, of their own accord, arrange to expand their autonomy in financial affairs and decide the amount of funds to be

retained by the enterprises. In expanding autonomy for running business, the enterprises have the right to arrange in a flexible way the variety of goods, the kinds of service, business hours and the way of running business, according to the situation of the market and the needs of the masses. In accordance with the rational orientation of goods and economic accounting, the enterprises have the right to select superior quality goods when purchasing the goods outside the plan from places of their choice. The enterprises should be given the right to control prices in a flexible way within a certain range. The prices of commodities of the third category purchased from elsewhere may be decided by the enterprises themselves, so long as these prices are below those of the local commodities of the same category and quality. The enterprises may reduce the prices of commodities which are damaged or have turned bad and which are unsalable or out of season. The enterprises should be given certain autonomy in labor management, including the autonomy to decide on and readjust labor organization. Under the quotas permitted by the state, they have the right to select good staff and workers for employment and to reward or punish staff and workers.

(2) They have set up a sound management system in various aspects. 1) They have set up a post responsibility system. The secretary, manager, accountant, buyer, counter group leader, warehouse keeper and seller have their own definite responsibility with each task being fulfilled by one person and publicized so that supervision can be carried out by the masses. 2) They have clearly stipulated regulations on a checking and reward system. They have worked out specific rules for checking and reward and punishment for the counter groups and staff and workers on how they fulfill their various tasks. For instance, sales quotas are assigned to each shop assistant. There are specific standards for checking the number of persons at work, the counter discipline, mistakes and errors, the quality of service and the variety of commodities. This is taken as a basis for the discussion of rewards to be issued to the staff and workers. Some stores have also carried out a 100-point system in recording the rewards. Thus the material interests of the staff and workers are closely linked with how business is run, and egalitarianism in allocation which was carried out in the past has now been changed. 3) Trial-point units have also intensified democratic management. Most of the units have elected counter group leaders and members of the Democratic Management Committee through democracy. The Tanggu District Jiefang Lu Department Store elected its manager through democracy. How the stores are run is closely related to the personal interests of the staff and workers, so democratic management is no longer a mere form, it has its concrete contents. Many staff and workers have made proposals to improve their work and expand business. Some stores have set up vocational research groups to find out about market supply and demand, to carry out market analysis and to advise the leadership.

(3) They have intensified ideological and political work. Trial-point units generally pay attention to doing a good job in ideological and political education, when carrying out the principle of material rewards. First is to make clear that the purpose of having trial points is not just for obtaining more money, but through the expansion of autonomy to further bring into play everybody's initiative, improve management, enhance the quality of service and serve production and the people's livelihood in a better way. Second is to carry out policy education and intensify the unity and mutual help among the staff and workers. Third is to cultivate advanced models, praise good people and good deeds in a timely manner and bring the initiative of the staff and workers into a correct orientation.

II

The carrying out of the trial point for being responsible for one's own profits and losses has closely linked the interests of the state, the interests of the enterprises and the interests of the individual. The enterprises' "power, responsibility and interests" are bound together. In this case, they have the internal motivation to run the enterprises well. The initiative of the staff and workers of the enterprises has been brought into better play and good results have been achieved.

(1) They have expanded business and enhanced the quality of service.

In the past, how the stores' business was run had nothing to do with the interests of the staff and workers. When business was run well and a lot of profits were realized, there was no increase in the income of the staff and workers; when business was run in a bad way and there was a decline or even loss in profits, the income of the staff and workers was not affected either. Therefore, only a few cadres were concerned with the purchase, marketing and stocking of the goods of the stores. The staff and workers very seldom paid attention to them. The shop assistants sold whatever had been purchased by the stores. Sometimes they did not even put the goods on the shelves until one design and color of goods was sold out. But now the situation has changed. Not only managers and counter group leaders pay attention to vocational work, but many staff and workers try every means to enliven business and do a good job in service. In respect of the origin of goods, they relied only on one channel, that is the wholesale departments. But now they can purchase goods by themselves. They can replenish their stock by buying goods from factories, foreign trade, street cooperatives, warehouses, communes and brigades and places outside Tianjin. The purchase procedures have been simplified and the variety of goods have been increased. Shop assistants not only supervise buyers in purchasing goods, but also go to the wholesale departments on their own initiative to check the variety of goods. They use various relations to open channels for the purchase of goods. The Shiyi Jinglu Department Store has established new relations for the purchase of goods with 28 units in the past 4 months and signed contracts with 14 units to act as an agent selling 89 kinds of commodities on a commission basis. The variety of goods being dealt with has amounted to 6,100 kinds, an increase of 24.3 percent over 1979 and 43.6 percent over 1978. The commodities purchased of their own accord have amounted to 254 kinds and 1.876 million yuan, which is 57.7 percent of the total volume of the goods purchased at the present stage.

In marketing, they have implemented the method of being diligent in purchase and quick in marketing and the method of small profits but quick turnover. They also do things for the convenience of the masses. For the convenience of customers, many stores and shops set up stalls to sell their goods, and according to the need of the customers, some stores and shops provide processing and repair services. The Shuguangli, Hongxiali and Daqing cake shops of Hexi District have extended their business hours. They send out people on their own initiative to factories, hospitals, streets and kindergartens to ascertain their needs. They deliver the goods to the door at an appointed time and place. In order to enliven business, Shiyi Jinglu Nonstaple Food Store has combined with Dagang Aquatic Breeding Farm in the suburbs in running a fresh water fish business. Qiandezhuang Nonstaple Food

Store and other units have set up market analysis groups whose members go to the wholesale departments, trade warehouses and free markets in the rural areas every day. They often visit the neighborhood residents and customers and investigate and study the trends of the changes in requirements, the situation of market supply and the situation of the changes in negotiated prices.

(2) They have strengthened accounting and improved the management of enterprises.

Before the trial points were carried out, the counter group of each store or shop generally had its own simple accounting, but the total accounting of various economic quotas was done by the accountant under the system of united revenue and expenditure and had little to do with the personal interests of the staff and workers, the system was often a mere form. In the present trial points, the stores or shops generally carry out the system of two-level accounting and management by the stores or shops and counter groups. The stores or shops convert the main economic quotas and service requirements into smaller quotas. Each group generally carries out the principle of "five fixes" (fixing sales, fixing profits, fixing cost, fixing mistakes and errors and fixing funds. Some units carry out the principle of four or six fixes). Responsibilities are assigned to each person. Marks and rewards are recorded related to the realization of quotas. For instance, Shiyi Jinglu Department Store carries out the principle of proportionate division of profits by the store and counter groups. The profits retained by the counter groups are used as rewards for the staff and workers. The Tanggu District Jiefang Lu Department Store issues rewards according to a certain rate of the total volume of sales. In addition, each store or shop has relatively expanded the counter groups' autonomy in running business (including the power to purchase goods, use funds, control expenses, handle damaged commodities and arrange personnel). Since the implementation of these methods, the staff and workers have become the masters; able to manage the affairs and property of the store and willing to put a lot of thought into how to enliven business and accelerate the turnover of funds. Once Shiyi Jinglu Department Store got a bank loan of 100,000 yuan to purchase from a foreign trade company a batch of children's acrylic sweaters and bed sheets which had originally been for export but had been shifted to the domestic market due to disqualification. According to the plan, they were to pay off the loan within 45 days. They mobilized all the staff and workers of the store to expand their sales by adopting the methods of small profits but quick turnover, of increasing the number of counters so as to accelerate the sales and delivery of the goods on their own initiative to the units under the system of collective ownership. For instance, according to the rules, the difference between wholesale and retail prices was 14 percent, but they altered it to 10 percent. As a result, the goods sold well and the turnover of these funds was accelerated. They paid off the loan within 12 days and gained profits of 20,000 yuan. Since the carrying out of accounting, a practice of thrift and diligence and of careful calculation and strict budgeting has been emerging. In the past, waste was rather serious in the use of packing materials in the Tanggu District Jiefang Lu Department Store. Now each group is responsible for the cost of packing materials. They carry out internal calculation of prices for packing materials. In the past 4 months they have saved more than 800 yuan in expenses for the cost of packing materials. The system in various aspects is well implemented, because the initiative and conscientiousness of the masses have been brought into play. In the past, no one cared for shortages of and damage to the commodities being stored. Now the receipt and delivery, storage, testing and examination of commodities are assigned to the persons concerned. Rules and regulations on rewards and punishment have been promulgated. Thus damage and shortages are reduced to the minimum. To balance the day's books has become the habit of the staff and workers of the store.

(3) The economic effect has generally been raised.

Various economic quotas of the trial-point units which are responsible for their own profits and losses are on the whole better than in the past. There has been a big increase in the volume of sales and profits. The turnover of the funds has been accelerated, the cost rate has been reduced and work efficiency has been enhanced. This change appears to be more outstanding if compared to that of nontrial-point units.

The following list shows a comparison between the various economic quotas of 10 trial-point units and of nontrial-point units. The percentage of increase and decrease from September to December 1980, is compared with the corresponding period of 1979.

	Undertakings of nonstaple food		Undertakings of general merchandise	
	5 trial-point units	6 medium sized markets	2 trial-point units	17 medium sized markets
Volume of sales	29.82	6.45	33.73	19.09
Work efficiency of all personnel	20.18	-1.93	39.59	11.29
Cost rate	-0.61	0.79	-0.21	0.06
Increase and decrease scale of cost rate	-11.02	13.93	-7.2	2.05
Profit rate of sales	1.63	-0.14	-0.25	-0.56
Increase and decrease scale of profit rate	41.05	-3.76	-4.19	-8.74
Number of days of turnover of funds	5.6	13.29	-4.33	3.24
Realized profits	82.81	2.45	28.07	8.69

	Undertakings of Candies and Cakes	
	3 Trial-point Units	Company System of Hexi District
Volume of sales	14	8.7
Work efficiency of all personnel	4.65	-2.77
Cost rate	-0.59	-1.03
Increase and decrease scale of profit rate	-9.15	-12.95
Profit rate of sales	1.82	0.58
Increase and decrease scale of profit rate	72.51	39.19
Number of days of turnover of funds	-3.1	16.12
Realized Profits	97.27	51.4

(4) There has been an increase in the income of the state, enterprise and individual.

According to statistics, the 10 trial-point units have turned over 769,000 yuan to the state within 4 months, a 35.27 percent increase over the corresponding period of last year.

In the past they carried out the principle of unified income and expenses, so the development funds and the collective welfare funds which could be allocated by the grass-roots stores were very small. They had to apply to the higher company for their expenses. Within 4 months, the 10 trial-point stores retained 92,000 yuan of enterprise development funds and 70,000 yuan of collective welfare funds for the enterprises' own allocation. These funds were used for expanding business, improving the working environment and increasing collective welfare institutions. It has solved some longstanding problems. With the development funds, both the Shiyi Jinglu Nonstaple Food Store and the Tanggu District Jiefang Lu Department Store have bought themselves a truck. The Shiyi Jinglu Nonstaple Food Store's original truck was dilapidated and they had to consign their goods for delivery. Sometimes delivery was not on schedule. The cost of freight for 1 year was so much that they could have bought a new truck with it. They applied to buy a truck a long time ago but were not permitted to do so. Now this problem has been solved. With the development funds, the Shiyi Jinglu Department Store has installed home-made radiators. With the welfare funds, they have structured the staff and workers' canteen and built a bathroom/shower unit. The long cherished hopes of the staff and workers have now been realized.

There has been an increase in the rewards issued to the staff and workers. Within 4 months of the carrying out of 10 trial-point stores, the average rewards for each person per month was 12.5 yuan more than in the corresponding period of the previous year.

There have also been some problems during the implementation of trial points, which must be studied and solved.

(1) Ideological and political work is not grasped firmly enough in some trial-point units. Attention is one-sidedly paid to profit quotas. There is a tendency to overlooking the socialist orientation of running a business. Very few units have resorted to unprincipled measures of running business and resorted to deception in order to make profits.

(2) Trial points are carried out only in a few retail units. The higher responsible departments such as the company of the district level, the company of the municipal level and the bureaus and wholesale departments concerned have not carried out the relevant reform work. Therefore, since the readjustment of the allocation of rights, limits and interests, contradictions between reform measures and the original system have emerged. From now on we should further study how to reform the whole circulation system and adopt appropriate measures to gradually solve this problem.

(3) The trial-point units have overcome egalitarianism in the issuance of rewards, and this has pushed the work forward. But the potential of some enterprises has not been fully estimated due to imperfections of some methods, and unevenness between hardship and happiness and the problem of rewards being a bit too high can still be found within the enterprises themselves and in a few units.

III

The practice of the trial points for a period of time has proved that in the two different forms of responsibility for one's own profits and losses, there is no difference in essence between the proportionate income tax and the original total volume of profits retained, except for changing the form in which the profits are turned over to the state into income tax. The carrying out of the method of "five taxes and one charge" is a step forward from the principle of retaining the total volume of profits, because the calculation of tax in the "five taxes and one charge" is based not only on the volume of the enterprises' profits but also on the volume of sales, the volume of profits, the area of the premises and landed estate and the amount of circulation funds which are used by the enterprises. Thus they have further broken away from the convention of "unified income and expenses" and have linked "power, responsibility and interests" more closely. It is far superior to the principle of retaining profits and of proportionate income tax.

First, it is beneficial for guaranteeing the stability of state revenue. The enterprises should pay taxes to the state, no matter whether they run their business well or not. In addition to industrial and commercial tax, there are readjustment tax, house property and landed estate tax and the charge for using circulation funds.

Second, it is beneficial for encouraging the enterprises and the staff and workers to further improve the management of enterprises. They should strive not only to increase the volume of profits, but also to reduce the cost, accelerate the turnover of funds and raise the profit rate of funds and profit rate of sales. In carrying out this method, the proportion of tax paid to the state per month varies as to how business is run in that month. If business is good, the enterprises may not only raise the amount to be retained but also exceed the originally proposed proportion to be retained. On the contrary, if business is not good, the enterprises may reduce the proportion to be retained. For instance, the Shiyi Jinglu Department Store precalculated that the proportion to be turned over to the state was 70 percent. The proportion of tax actually paid for the months of September, October, November and December was respectively 67.67 percent, 71.68 percent, 68.17 percent and 71.7 percent; Shiyi Jinglu Nonstaple Food Store precalculated that the proportion to be turned over to the state was 60 percent. The proportion of tax actually paid was approximately 55 percent. In this way they have changed more effectively the situation in which they ate out of a big pot and had a "guaranteed income come rain or shine."

Third, some units carry out the method of retaining base profits plus the dividing the part that is overfulfilled. Because the sales plan and the volume of profit quotas have much to do with the amount to be retained by the enterprises, endless arguments often occur when deciding the quotas for the plan. Because the quotas are often inappropriate, the profits retained by the enterprises are too high at one time and too low at another (it is more often that they keep the quotas very low so as to retain more profits for the enterprises). The carrying out of the principle of "five taxes and one charge" can prevent such a tendency, because the quotas for the plan do not have much effect on the profits to be retained by the enterprises.

Fourth, proportionate income tax is not easy to popularize, because each store or shop has its own tax rate. The principle of "five taxes and one charge" is easy to popularize, because the tax rate and cost rate are unified, except for the readjustment tax.

If viewed from the results, two types of stores responsible for their own profits and losses do not differ much on the whole. But one factor must be taken into consideration. The Shiyi Jinglu Department Store and Shiyi Jinglu Nonstaple Food Store which carry out the principle of "five taxes and one charge" have increased their business operations by a large margin due to the trial-implementation of the principle of profits retention in the fourth quarter of 1979. There was a further increase after the implementation of the principle of "five taxes and one charge" in 1980. Therefore the enhancement of the economic results is more outstanding, if we consider them altogether in unification. From September to December, 1980, the volume of sales and the volume of profits of the Shiyi Jinglu Department Store were up by 84.3 percent and 153.8 percent respectively in comparison with the corresponding period of 1978, and those of the Shiyi Jinglu Nonstaple Food Store were up by 23.7 percent and 48.3 percent respectively.

Of course, it is still necessary to further perfect the method of "five taxes and one charge." Some problems have still to be studied and solved in practice. For instance, there are great differences in the profit rates of different undertakings. Take the two trial-point undertakings of the department store and the nonstaple food store as an example. The nonstaple food store belongs to the undertaking of small profits. If it is required to pay income tax according to the unified tax rate, the profits retained by the enterprises will be very small. In addition, the store has to keep the rewards for the staff and workers at a certain level, so the amount of the development and welfare funds the enterprises can retain is very small. That is detrimental to the development of the store itself. Therefore, it is possible to consider the adoption of different tax rates for different undertakings. We should further study how to rationally analyze the subjective and objective reasons that cause the difference in revenue and to maintain the tax rate of the readjustment tax on the differential revenue so as to let the state take the greater part of the differential revenue that is not caused by subjective reasons, while maintaining the initiative of the staff and workers of the stores that have been doing well in their business.

On the basis of the method of "five taxes and one charge" that was implemented last year, the Tianjin Finance and Trade Commission will, beginning this year, change the method of collecting "house property and landed estate tax" into that of collecting the "cost for the use of fixed assets," which will be collected at a monthly rate of 3 per mill based on the original value of the enterprises' fixed assets provided by the state (including buildings, machinery and equipment). In addition, the proportionate income tax that was originally implemented in eight units will all be changed to the method of "four taxes and two charges."

IV

The trial points have just been carried out in a few units and the achievements are only preliminary. There are certain limitations to them. From the practice within these few months, we have learned the following points:

(1) The question of solving the form of the system of ownership of the retail trade includes the two tasks of developing the component part of the diversified economy and of perfecting the form of the system of ownership by the whole people.

The retail trade is an important link in the process of social reproduction. After social products are produced, they must go through circulation and enter the sphere of consumption so as to become objects of consumption. The retail trade is just a link that ultimately has decisive singificance in the circulation process of commodities. It not only takes on the circulation of the means of livelihood, but undertakes part of the means of production (this is especially so in the countryside). On the one hand, it links up with industrial and agricultural production through the wholesale trade. On the other hand, it directly serves the daily needs of the people. Doing a good job in the retail trade has important significance to meeting the demands of the people's livelihood, promoting the development of industrial and agricultural production, establishing close ties between the party and government and the people and to reflecting the superiority of the socialist system. Under the protracted influence of "leftist" ideology, the retail trade network was removed and merged in such a big way that the stores became bigger and bigger and the network became smaller and smaller. In this case, they were far from being able to meet the needs of the consumers. As they were overanxious about the reform of the ownership system, many cooperative shops were changed into state-run shops, while the rest were changed into large collectively-owned shops, which carried out the principle of unified responsibility for profits and losses. Individual small merchants and peddlers practically disappeared. In fact business was exclusively run by state-owned trade. In the management system, power was excessively centralized. The enterprises had no autonomy and carried out the principle of eating out of a big pot and of egalitarianism in allocation, which seriously hampered the initiative of the staff and workers of the enterprises. This gave rise to a situation in which the quality and attitude of service in the retail trade were bad, "bureaucratic style of work in business" was serious, management was in such a mess that there were loopholes, losses and waste and that the results of running business were bad. All this affected the character of the ownership system in socialist trade in such a way that it was hard for the retail trade to meet the needs of industrial and agricultural production and the people's livelihood. The masses had a lot of complaints about it. In readjusting the national economy, we should not only readjust the proportionate relations, appropriately increase the investment in and labor force of the retail trade and increase the network so as to adapt the scale of trade to production and consumption, but also solve the form of the ownership system in the retail trade so as to adapt the production relations to the level of the productive forces. We have to do it from two aspects. On the one hand, we should readjust the structure of the ownership system, energetically develop collective trade, and appropriately develop individual trade so as to make the component parts of a diversified economy coexist with each bringing into play its characteristics. On the other hand, we should investigate and study some appropriate specific forms in the state-run retail trade so as to bring into better play the initiative of the enterprises and the staff and workers, improve management and meet the needs of the masses in a better way. Therefore, we must fundamentally restructure the management system of stores or shops and carry out the principle of independent accounting, of the substitution of taxes for profits and of being responsible for one's own profits and losses. We must further get rid of the convention of unified income and expenses. This will give more impetus to encouraging the staff and workers in the commercial field to improve their management system and service.

(2) The principle of being responsible for one's own profits and losses carried out by the state-run stores is a principle of being responsible for one's own profits and losses in a relative sense. It is the consummation of the form of the system of ownership by the whole people. According to the objective requirements of the socialist commodity economy, each basic economic unit should have certain autonomy for its economic activities and become a relatively independent commodity producer which shoulders the relevant economic responsibilities. Take the concrete example of the retail trade, medium and small enterprises are in the majority, the places where they are located are separated from each other and there is a great variety of business and service items. They face large numbers of consumers, they should not adopt an accounting form of high centralization and of unified responsibility for profits and losses. The carrying out of the system of being responsible for one's own profits and losses is beneficial for bringing into better play the initiative of the staff and workers, to meet the immense variety of customers' demands. This is more suitable to the characteristics of the retail trade.

Viewed from the situation of the trail points, we know after the stores have carried out the system of responsibility for their own profits and losses, first, the ownership of the means of production still belongs to the state; second, although the right to use the means of production belongs to the stores, the stores still have to carry out business under state planning and within the limits permitted by policies and decrees, and they have to shoulder the relevant economic responsibilities. The stores cannot go beyond the range of business, nor have they the right to use the means of production for speculation and profiteering, for harming the people's interests or for seeking personal gain. In other words, the stores make use of the right under certain conditions. Third, the allocation of the income and profits of the stores is carried out under the principle of considering the interests of the state, the collective and the individual and in accordance with the rules and regulations concerned. From September to December 1980 the income of Shiyi Jinglu Department Store increased by 66,000 yuan over the corresponding period of the previous year. In all, 42,800 yuan, which was 64.8 percent of the increased amount, was turned over to the state. The income of Shiyi Jinglu Nonstaple Food Store increased by 17,300 yuan over the corresponding period of the previous year. In all 15,200 yuan, which was 87.6 percent of the increased amount, was turned over to the state. Except for the greater part of the enterprises' profits which were turned over to the state, the fixed assets and welfare institutions purchased with the enterprises' retained funds are still the property of the system of ownership by the whole people. From the various aspects mentioned above, we know that the trial-point stores carry out the system of responsibility for their own profits and losses under relative and certain limits. This system only changes the management system and form of allocation of the stores, making the production relations of the system of ownership by the whole people more perfect. It does not change the nature of the system of ownership by the whole people of the enterprises.

(3) We should further study how to realize macroeconomic targets while enlivening microeconomics.

The purpose of carrying out the system of responsibility for enterprises' own profits and losses and of perfecting the system of ownership by the whole people is to bring into play the initiative of the staff and workers of the enterprises, to enliven the economy, to promote production and to meet the needs of society. The facts obtained from the trial points show that realizing the target of meeting the needs of society is fundamentally identical with improving the way of running business and increasing profits. But there is a contradictory aspect between increasing the enterprises' profits and meeting the needs of society. Therefore, the enterprises have enlarged their autonomy in running business, and the income of the staff and workers is closely linked with profits. Under the condition of having greater motivation, how should we intensify the state's instructions to and control over the enterprises' economic activities to prevent the tendency of just concentrating on profits and of neglecting the need of society; how should we make the enterprises not only have powerful motivation but also keep on the right track; how should we make the enterprises' economic activities comply not only to the requirements of the law of value and of the law of material interests, but primarily to the requirements of the basic law of the socialist economy to differentiate them from capitalist trade which is intent on nothing but profits; these are problems which merit further study and solution.

In order to realize the above, the fundamental guarantee is to do a good job in readjustment, to stabilize macroeconomics, to have a rich supply of the means of livelihood, to make the trade network sufficient and to open up and unblock the circulation channels. In this way, speculation and profiteering, the forcing up of prices and the practice of concentrating on high profits will be restricted to a very great extent.

In order to carry out the above, we should make clear the enterprises' responsibilities and work out practicable, all-round checking and supervision methods, while expanding their autonomy. We should check not only on profit and other economic quotas, but also on how the principles of running business and policies are implemented, and on how service is improved so as to meet the needs of society. We should direct the initative of the staff and workers of the enterprises onto the right track.

Units at a higher level should exercise the necessary administration over the enterprises which carry out the system of responsibility for their own profits and losses. They should instruct and restrict these enterprises through economic levers such as prices, credit and taxation. Economic legislation, such as legislation on fixing prices and legislation on market management, should be intensified. Those who act against such legislation will be given economic and legal sanctions.

Trial points have just been carried out, many problems cannot be deeply studied and summed up in time. We will work out a comprehensive and complete system and methods through accumulation of experience in our practice in the future, so as to guarantee that the enterprises which carry out the system of responsibility for their own profits and losses can advance along the correct road of serving the people.

'JINGJI YANJIU' ON SUPERIORITY OF SOCIALISM

HK311313 Beijing JINGJI YANJIU [ECONOMIC RESEARCH] in Chinese No 7, 20 Jul 81 pp 34-39

[Article by Zhou Zhenhua [0719 2128 5478] of the Scientific Socialism Research Institute of the Sichuan Provincial Academy of Social Sciences: "Several Questions Concerning the Superiority of the Socialist Economic System"]

[Text] The "resolution on certain questions in the history of our party since the founding of the People's Republic of China" passed by the 6th Plenary Session of the 11th Party Central Committee Party incisively summed up the positive and negative historical experiences over the 32 years since the founding of the People's Republic, systematically expounded on the superiority of our socialist economic system and explicitly set forth the historical mission of further bringing into play the superiority of the socialist system and gradually building our country into a modern, highly democratic and highly civilized great power. We must seriously study and firmly implement these documents, bolster our confidence, heighten our spirit, more closely unite around the Party Central Committee, act with one heart and one mind and advance in victory along the party's line laid down since the 3d Plenary Session of the 11th Party Central Committee.

This article intends to present the author's insights and some tentative views after studying these documents, focusing on the following question: What are the major manifestations of the superiority of the socialist economic system? Why is it that some aspects of this superiority were not fully brought into play in our country during certain periods? What are the ways by which the superiority of the socialist economic system can be more fully brought into play?

(I)

Marx' and Engels' theory on the superiority of a socialist economic system is based on scientific knowledge of the objective law of development of human society. It was formulated by contrasting the socialist system with the basic contradictions and decadence of the capitalist system.

Marx and Engels pointed out that the basic law of development of human society is that production relations must be compatible with the nature of the productive force and that socialized mass production and class contradictions under the capitalist system will certainly lead to the dictatorship of the proletariat and the replacement of the capitalist economic system by the socialist economic system. While exposing the decadence of the capitalist economic system, they also expounded on the superiority of the socialist economic system. They pointed out that under the capitalist system, the process of production is highly socialized while the means of production is concentrated in the hands of a small number of capitalists, and the goal of production is to exploit the surplus value created by the proletariat. On the other hand, the socialist economic system achieves public ownership of the means of production on the basis of socialized mass production and eradicates the phenomenon of man exploiting other human beings. This is "the only precondition for the constant and rapid development of the productive force." The goal of developing production is to "ensure that all members of society can enjoy a prosperous and ever richer material life and that they can fully and freely develop their physical prowess and intelligence." ("Anti-Duhring," "Selected Works of Marx and Engels," Vol 3, p 322) Under the capitalist system, the capitalists engage in unbridled competition on the basis of the system of private ownership of property periodic economic crises caused by the anarchic state of production bring about serious disruption to the productive force. Under the socialist economic system, "the anarchic state of social production gives way to socialized and planned regulation of production according to the needs of the whole society and each individual member." The people "become the masters of their own social association" and "create their own history with full consciousness." (Ibid, pp 319, 323) Under the capitalist system, "those...who work acquire nothing, and those who acquire anything, do not work." ("Selected Works of Marx and Engels," "The Communist Manifesto," Vol 1, p 267) Under the socialist economic system, "the individual producer receives back from society--after the deductions have been made--exactly what he gives to it. What he has given to it is his individual quantum of labor." "He draws from the social stock of the means of consumption as much as the same amount of labor he contribures costs." ("Selected Works of Marx and Engels," "Critique of the Gotha Program," Vol 3, pp 10-11) Under the capitalist system, the bourgeoisie ruthlessly oppresses and enslaves the working people; the socialist system "raises the proletariat to the position of the ruling class, to win the battle of democracy." Under this system, "the free development of each is the condition for the free development of all." ("Selected Works of Marx and Engles," "The Communist Manifesto," Vol 1, pp 272-273)

From the above discussion, the superiority of the socialist system which Marx and Engels expounded on is mainly manifested in the following three aspects: Economically, it realizes the public ownership of the means of production, and the regulation by planning and distribution according to work, enables the productive force to develop constantly and rapidly and make it possible for the people to enjoy a prosperous and increasingly better material life. Politically, it fully brings people's democracy into play and enables the people to become the real master~~s~~ of society. Culturally, it enables full and free development and utilization of the people's physical prowess and intelligence. It is precisely because the socialist system possesses superiority in many aspects that it will ultimately overcome the capitalist system.

(II)

For the socialist economic system to fully manifest its superiority over the capitalist economic system, it has to undergo a long and tortuous historical process.

What is the criterion in determining whether a new social economic system is better than an old social economic system? Basically, we have to see within a very long historical period whether the production relations in this society are more compatible with the nature and level of development of the productive force than in the old society, whether they can better mobilize the workers' enthusiasm and whether they can rationally utilize the means of production to realize the development of the productive force faster and on a larger scale than in the old society. We must not take specific phenomena during a specific period, in a specific country or in a specific area as the criterion for judging whether a social economic system is superior or not. Otherwise, we will be confused by superficial phenomena and will not be able to see the true nature of matters with clarity.

Stalin said: "It took the feudal economic system around 200 years to prove its superiority over the economic system of the slave society...and the bourgeois economic system 100 years or less to prove its superiority over the feudal economic system." (Stalin: "On the Opposition," People's Publishing House 1963 edition, p 405) This is because all newborn social economic systems develop along a tortuous path. As the old social economic system approaches the brink of destruction, because of the old ruling class' rich experience in reactionary rule, it will try to enforce certain partial reforms and patch up its errors in order to prolong the measured days of the old economic system. At times, a sudden "spurt of vitality" might even occur prior to final collapse. On the other hand, when a new social economic system is born, because the new production relations and superstructure have not fully matured, it is still imperfect and has various shortcomings and errors, and because the new ruling class lacks leadership experience, various kinds of errors are inevitable and sometimes, even great setbacks and retrogressions occur. Nevertheless, as the basic economic system of the old society is incompatible with the nature of the productive force, even if some of its specific structures are almost perfect, it will still be unable to resolve this inherent contradiction and its advance toward destruction is inevitable. As for the new society, although its specific structures have not fully matured and have imperfections, because its basic economic system is cimpatible with the need to further develop the productive force and with the basic interests of the broad masses of people and because it represents the direction of historical progress, it will be able to overcome the shortcomings and errors of its specific structures and constantly improve and develop itself in the course of advance, ultimately overcoming the old social economic system and bringing human society onto a new and higher state.

Marx' and Engels' exposition on the superiority of the socialist economic system was formulated according to the conditions prevailing during the 19th century and on the assumption that the proletarian socialist revolution would first triumph in developed capitalist countries such as Britain, the United States, France and Germany. Great machines and industries had been built in these countries; the productive force was highly developed; the proletariat constituted the majority or a significant portion of the population; the people's scientific and cultural level was relatively high, and they had a long tradition of democratic political life. Marx and Engels thought that after the proletariat in these countries seized political power, expropriated the capitalists and reformed the small producers, the superiority of the socialist economic system would be significantly manifested in a relatively short period of time.

However, history traveled along a tortuous path. After Marx and Engels died, two events in historical development which they had not anticipated occurred: One was at the end of the 19th century and the other some time after the mid-20th century. Two industrial revolutions occurred in the capitalist world and production techniques advanced from the steam engine era to the electrical power era and from the electrical power era to the era of atomic power; while economically, the capitalist world advanced from free capitalism to the stage of monopoly capitalism and from monopoly capitalism to the stage of state monopoly capitalism. Thus, although there has been no qualitative change in the basic capitalist economic system--the system of private ownership of the means of production and the exploitation of the surplus value created by the proletariat--great changes have occurred in many specific structures of the capitalist economy. Essentially, this is a system wherein "the bourgeoisie has progressively come to consider the productive force as a social productive force within all the possible limits of capitalist production relations" in order to continue the development of the productive force in capitalist countries and the improvement of the people's livelihood. ("Selected Works of Marx and Engels," "Anti-Duhring," Vol 3, p 317) Another event was that the socialist revolution had not been able to win simultaneous victory in the developed capitalist countries but first achieved victory in countries where the productive force was underdeveloped. The October revolution achieved victory in Russia where capitalism was at an intermediate stage of development while after the Second World War, the revolution achieved victory in China where the productive force was backward and also in other backward countries. In these countries, manual labor was still predominant; productivity was low; peasants and small producers constituted an overwhelming majority of the population; culture and science were backward, and there had been a long tradition of feudalism. After the proletariat seized power in these countries, they still had to conduct socialist reform of the bourgeoisie and the small producers and develop socialized mass production. Thus, it would take some time for the superiority of the socialist economic system as perceived by Marx and Engels to be fully manifested.

Therefore, our understanding of the superiority of the socialist economic system is not only based on the relvant expositions of the classical writers of Marxism. We must also start from reality and engage in concrete analysis of concrete problems. We must not see things only from a short-term perspective but also from a long-term perspective. We must not only look at the total production output and living standard of specific countries and areas but must also see whether the production relations (economic system) is basically compatible with the nature of the productive force and whether the political system and other parts of the superstructure can push forward the formation of the new economic base and promote the development of the productive force. In short, we must adopt the viewpoint and methodology of dialectical materialism in understanding the superiority of the socialist economic system and must not be confused by certain superficial phenomena.

(III)

Our socialist economic system was built and developed from the ruins of a semicolonial and semifeudal society where in the productive force was very backward. To fully demonstrate the superiority of our national economy in comparison with the national economy of capitalist countries will all the more require a long and tortuous historical process. This is a complex and arduous process.

The establishment and development of the socialist economic system in China was the inevitable outcome of our historical development. It was a decisive choice made by hundreds of millions of our people in the long process of struggle. Old China was a semicolonial and semifeudal society. Over more than 100 years, many progressive people took the old road of European, American or Japanese capitalist modernization in their effort to break away from the backwardness of the economy and technology. However, they all failed. The only road could be transition to socialism from new democracy under the leadership of the CCP and the establishment of a modern socialist power where man does not exploit other human beings.

The history of the People's Republic of China over the past 30 years or so is a history of great victories in socialist revolution and socialist construction. We have established the socialist state system wherein the people are masters under the leadership of the proletariat. We have established a socialist economic system consisting of state ownership and collective ownership. We have also established an independent and relatively complete industrial and national economic system and laid the initial foundation for the realization of modernization.

Practice in the past 32 years has initially proved the superiority of our socialist economic system. Although the development of our national economy experienced several complications, we were still able to attain achievements which would have been impossible in old China. From 1950 to 1977, total industrial output in our country grew by an annual rate of 13.5 percent. During the same period, the industrial growth rates in some capitalist countries were as follows: 4.5 percent for the United States, 12.4 percent for Japan, 6.9 percent for West Germany, 2.3 percent for Great Britain and 5.2 percent for France. Our total agricultural output increased by an annual average of 4.2 percent. During this period, agricultural growth rates in some capitalist countries were: 1.9 percent for the United States, 2.7 percent for Japan, 1.8 percent for West Germany and 2.2 percent for both Great Britain and France. Relying on our own resources, we established a series of new industrial and communications sectors and scientific and technological departments, succeeded in testing the atomic bomb, the hydrogen bomb and the ICBM and launching and retrieving artificial earth satellites. The material and cultural life of the great masses of our people has considerably improved compared with the period before liberation. This fully shows that our socialist economic system--public ownership of the means of production, regulation by planning and distribution according to work--has great vitality. It is indubitable that we can rely on the superiority of the socialist economic system to achieve the four modernizations. All views which negate the superiority of the socialist economic system are erroneous.

However, we must also see that at the present stage, many shortcomings and weak points still exist in specific structures of our socialist economic system. The major faults are: Too much rigidity in the system of economic management, overcentralization in the system of planning, egalitarianism in the wage system and others. The existence of these faults also seriously impedes the full manifestation of the superiority of the socialist economic system.

In short, we must take the viewpoint of dividing one into two in understanding the socialist economic systems established by countries whose productive force is underdeveloped. First, we must fully affirm that their basic system--public ownership of the means of production, regulation by planning and distribution according to work--is essentially compatible with the socialized productive force, and thus, the socialist economic system possesses great vitality. At the same time, we must be sober-minded and see that shortcomings and faults still exist in specific structures in this system and that they are incompatible with the growth of the productive force and hinder the full realization of the inherent superiority of the socialist economic system. The main reason why these shortcomings and faults exist is that without regard to the conditions prevailing in our country, we arbitrarily designated the superiority which Marx and Engels mentioned and which can only be realized in a developed and mature socialist society as a goal which can be attained in our country at the present stage. We committed leftist errors in the guiding principles of economic construction.

(IV)

The basic way to fully realize the superiority of our socialist economic system is to actively and steadily engage in economic readjustment and economic reform in accordance with the requirements of the development of the productive force.

In human history, all social economic forms had to constantly enforce readjustment and reform of their specific structures on the basis of their fundamental economic system. Compared with the qualitative change of developing from one social economic system to another--a "leap"--this readjustment and reform of specific economic structures is but a quantitative change or partial qualitative change, but it is nonetheless an indispensable link in the process of development of production. We must be good at distinguishing between the basic system of a social economic form and its specific structures. The incompatibility of the basic system with the productive force can only be resolved through a social revolution or by eliminating the old production relations. This is a stage when the contradiction between production relations and the productive force is in a stage of significant flux and a state of dundamental change wherein one social economic form replaces another, such as the socialist system replacing the capitalist system. Once a new social economic form has been established, its basic system is relatively stable and will not undergo fundamental qualitative change within a whole historical period. However, the productive force is the most revolutionary and most active element in social production. Many aspects of specific structures will become incompatible with the development of the productive force. This incompatibility between specific structures and the productive force can be resolved in time by enforcing partial readjustment and reform while maintaining the basic system of the social economic form. This is the "evolutionary process" in the historical development of society. It is a stage when the contradiction between production relations and the productive force is in a state of quantitative change or partial qualitative change. It is definitely not the negation of the basic economic system but an effort to improve it and make the basic economic system more sophisticated.

The socialist economic system is a new economic system in human history and one that is more advanced than capitalism. Its birth, development and change will take several hundred years and there will certainly be different stages of growth. In the entire historical process of socialist society, the basic economic system--public ownership of the means of production, regulation by planning and distribution according to work--will not undergo any fundamental change. However, specific economic structures will undergo changes at every stage of its growth. Partial readjustment and reform must be undertaken to cope with the requirement of the development of the productive force. If people can undertake readjustment and reform of specific structures in the socialist economy, the inherent superiority of the socialist economic system will be better brought into play.

Public ownership of the means of production is the cornerstone of a socialist economic system. Our determination to maintain socialist public ownership does not mean that we believe that the higher the level of public ownership the better, without considering the actual conditions of the productive force. It means the establishment of a system of ownership which is suited to the state of the productive force in our country at the present stage, by observing the law that production relations must be compatible with the nature of the productive force. We have a population of 1 billion, 800 million of whom are peasants; we have a vast territory but little arable land; our economic foundation is weak; manual labor still predominates; the commodity economy is backward; the level of socialization of production is low and the development of the productive force is very unbalanced. Under such conditions, we can only establish a system of ownership consisting of diversified economic elements and coexisting forms of diversified modes of production with the socialist state economy and collective economy as its main body and state capitalist economy under the guidance of state plans and individual economy as its complement. Only thus can we fully make use of the abundant manpower and material resources in our country to create more material and spiritual wealth in order to satisfy the growing material and cultural needs of the whole society.

A socialist state-owned economy is the leading strength in our national economy. To make the specific structures in the socialist state ownership system compatible with the state of the productive force at the present stage, we must steadily enforce comprehensive reform of the economic management system. Through expanding the decisionmaking power of enterprises, we must set up the system of "substituting taxes for profits, independent accounting and responsibility for one's own profits and losses" in order to transform the enterprises from being attachments of administrative organs at various levels into relatively independent commodity producers under the guidance of state plans which are able to flexibly conduct productive activities in accordance with social needs and which are able to closely relate production results with the material interests of the enterprise and the workers. On the basis of expanding the decisionmaking power of enterprises, we must change unilateral reliance on regulation by planning into combining regulation by planning mechanism with regulation by market mechanism. Economic management must move from mainly relying on administrative organization and measures to relying on economic organization and measures. We must remold enterprises which are "big and complete" or "small but complete" into integrated economic entities which are organized according to the principles of specialization and coordination and economic rationalization. These measures must be taken to make our economic management system and operation and management methods compatible with the requirements of building the four modernizations and to promote the continuous and steady growth of our productive force.

The improvement of the system of ownership and the reform of the economic management system are closely related and complementary to the readjustment of the structure of the national economy. Under the present conditions of irrational structure of the national economy and serious disequlibrium in the proportional relationships, readjusting the national economy is the foremost task. All efforts to improve the system of ownership and to reform the economic management system must be subordinated to readjustment, must serve readjustment and must be smoothly conducted in a way beneficial to readjustment. Some measures which ought to be taken from the long-term point of view but which conflict with present readjustment work must be postponed. Measures which are also beneficial to the readjustment work must be continued. In order to solve the problem of disequilibrium in the national economy once and for all, the ownership system must be improved and the economic management system must be reformed. Only by maintaining the absolute primacy of socialist public ownership while enforcing various types of responsibility systems and appropriately expanding private plots in the rural areas, permitting the existence of individual economy and vigorously developing collective ownership in the urban areas and adopting state capitalist economy by engaging in joint ventures with foreign capital can we enliven the economy, increase income, increase accumulation, overcome financial and economic difficulties and develop the weak links in the national economy. By the same token, it is only by seriously reforming the economic management system which is characterized by a high degree of centralization, unified control of income and expenditure and state monopoly of purchase and marketing can we fully mobilize the enthusiasm of central departments, local administration at various levels, enterprises and producers, do a good job in combining the strengthening of macroeconomic guidance by state plans and the enlivening of microeconomic enterprises and greatly improve the economic results of production and construction, to enable the socialist economy to develop rapidly.

In short, the errors and setbacks in our economic construction and economic work were not brought about by the basic economic system of socialism but were caused by the shortcomings and faults of specific structures in the socialist economy. Our country has not yet been engaged in socialist construction for a long time. We are clear about certain laws of development of the socialist economy, while with regard to many others, we have to undertake further research. It is inevitable that in the process of building modernization in a vast socialist country like ours with a population of 1 billion, 800 million of whom are peasants and a backward economy that some errors appear in our work and some shortcomings exist in the specific structures of the socialist economy. The reason why we are rectifying the leftist errors in economic construction and enforcing a series of economic readjustments and reforms is definitely not to change the basic system of our socialist economy but to overcome the shortcomings and faults in specific structures, avoid repeating past setbacks and mistakes and gradually enable the inherent great superiority of the basic system of socialist economy to be fully brought into play. Therefore, those views which hold that readjustment and reform are "rightist" and "revisionist" are erroneous. Those who think that readjustment and reform mean adopting the methods of capitalist economy and abandoning the basic system of socialist economy are even more mistaken.

Engels said: "The best way to clearly understand theory is to learn from one's own mistakes and painful experiences." ("Selected Works of Marx and Engels," "To Mrs F. Kelley-Wisch-Newetzky (28 December 1886)," Vol 4, p 458) Since the 3d Plenary Session of the 11th Party Central Committee, the Party Central Committee has seriously rectified leftist errors and gradually established a road to modernization which is suited to conditions in our country. Although this has to be constantly developed, enriched and improved in the process of practice, the important points have been summed up and have been confirmed in the "resolution on certain questions in the history of our party since the founding of the People's Republic of China," which was adopted during the 6th Plenary Session of the Party Central Committee. This is an important guarantee for the further demonstration of the superiortiy of the socialist economic system and the achievement of the victory of building the four modernizations.

Under the leadership of the Party Central Committee, we must consciously implement the party's line since the 3d Plenary Session of the Party Central Committee, firmly march forward along the road of socialism and struggle hard to build a highly democratic, highly civilized and great modern socialist power.

1980 POWER INDUSTRY ENERGY CONSERVATION RESULTS, NEW TASKS SURVEYED

Beijing DIANLI JISHU [ELECTRIC POWER] in Chinese No 6, 5 Jun 81 pp 1-2

[Article by editorial staff: "Strive to Decrease Energy Consumption in Electric Power Industry"]

[Text] In 1980, staff and workers on the electric power production front engaged in energy conservation work, achieving rather good results. The nation's fossil-fired power plants with capacities of over 6,000 kW achieved a fuel consumption rate of 448 g/kWh lower than in the previous year, which resulted in a saving of 2.9 million tons of raw coal. Actual line losses in the power grid were decreased to 8.93 percent, a figure 820 million kWh lower than in the previous year and equivalent to a saving of 450,000 tons of raw coal. By rational water use, large and medium size hydroelectric stations generated an additional 1.6 billion kWh of electricity, equivalent to 960,000 tons of raw coal. Fuel oil consumption in fossil-fired plants was decreased by 580,000 tons from the previous year, equivalent to 1.1 million tons of raw coal. With the exception of the saving on oil, which resulted from the change in consumption structure embodied in the state energy policy of converting oil-fired turbines to coal and which thus cannot be counted as conservation (although it does include the conservation of ignition oil in some fossil-fired plants), the conservation results for last year were equivalent to a saving of 4.31 million tons of raw coal nationwide, or about 3.5 percent of the total amount of coal used nationwide for generating electricity and providing heat through the heating network. This must be called a considerable conservation achievement.

Analyzing the various energy conservation measures, it becomes clear that the greatest conservation effect was achieved by decreasing coal consumption in electric power production nationwide, and that increased use of high-temperature, high-pressure generating units played the main role in this saving. Because high-temperature, high-pressure units can decrease coal consumption by about 160 g/kWh as compared with low-pressure equipment, economic load scheduling throughout the nation's electric power system last year increased the amount of energy generated with high-pressure units (not including high-pressure block capacities first commissioned during the year) by more than 10 billion kWh over the previous year; this factor alone accounted for 80 percent of the total saving of raw coal in fossil-fired electrical power production. The next most important factor was the relatively long high-water season and abundant water, as a result of which the electric power systems were able to practice rational load scheduling and produce more electricity. Last year, national power production was up 8.3 billion kWh, and a mere 26 large and medium reserviors not only yielded more than 4 billion kWh of additioanl hydroelectric power, but also stored an extra 11.4 billion cubic meters of water. The restoration of water levels in the reservoirs laid an excellent foundation for thorough, rational utilization of hydroelectric resources this year. As a result, we should make even better use of the potential represented by high-pressure generating units and hydroelectric power generation to achieve even better conservation results.

Energy conservation is an undertaking in which the masses should participate. Experience shows that if all power industry employees had not striven to utilize latent potential and had not done everything possible to save the energy contained in coal, electricity, oil,water and steam, it would have been impossible to accumulate such great conservation results. According to summary data on large-scale repair of fossil-fired electric power units in 1980, more than 1,400 turbines and boilers were given major overhauls nationwide, while in coordination with these overhauls, various types of measures were taken to improve technology in order to increase safety and save on energy. Plastic ball cleaning apparatus was installed on the condensers of more than 40 units, making possible an increase of about 2 percent in the vacuum in the units; more than 200 blowers and 300 water pumps were modernized, generally resulting in a saving of 1 to 2 percent on electricity use by the plants themselves; the overhauls of turbine and boiler equipment eliminated leakage and failures; and some of the equipment was subjected to thermal efficiency testing, resulting in improvement of efficiency everywhere.

In order to give a clear idea of the latent potential for energy conservation, we now present some examples of conservation results.

As a result of overhaul and modernization of two 300,000 kW units at the Wangting power station, the period of safe operation was further increased, and in particular after a high-pressure heater was put into operation in one of the units, the output of that unit reached essentially the rated value, the feedwater temperature was increased from 160° to 260°C, and the unit's heat consumption fell from 2,213 to 2,158 kcal/kWh, resulting in a decrease of 10 g/kWh in coal consumption which made it possible to save more than 400 tons of standard coal a day. It can be seen from this example that installing high-pressure heaters is very important in fuel conservation.

Because of limitations in the original set of equipment of a 75,000 kW generator unit at the Jinan power plant, for a long time the power output was 50,000 kW and the turbine steam consumption rate was about 3.5 percent above the guaranteed factory figure, while the turbine efficiency was about 2 to 3 percent below the design figure, so that this unit had the highest coal consumption in the plant. In order to save fuel, the power plant took the occasion of a major overhaul to readjust the set of equipment, decrease the number of nozzles, decrease the flow surface in all stages, eliminated vacuum system leakage, repaired gaps in the axle seals, improved the tightness of the rotary air preheater and the like, with the result that the turbine's heat consumption decreased by 130 kcal/kWh, the turbine efficiency was increased by 2 percent and the fuel consumption for the unit fell by 25 g/kWh, so that this unit, which originally had had the lowest efficiency, suddenly became the most efficient unit, yielding a saving of more than 200 tons of standard coal a day. In fact, in the past many power plants practiced "above-rating" operation on a large scale, increasing the nozzle area in the diaphragm, which resulted in great steam losses; an analysis by the Northeast Electric Power Technology Improvement Office indicates that simply by returning to the initial flow area certain plants in the northeast could save about 10,000 tons of standard coal per year.

The Baiyang River electric power plant put an unused small 1,500 kW steam turbine into use and converted a DG-270 electric feedwater pump into a gas-powered pump; the increase in gas consumption resulted in an increased coal consumption of 1.5 g/kWh, but a decrease in the plant's electric power consumption resulted in a drop of 2 g/kWh in the coal consumed in energy production. As a result of improvements, the plant can produce more than 20,000 additional kilowatt-hours of electricity a day and can save about 0.5 tons of standard coal. Recently after the Minhang power station began using a hydraulically-coupled speed-adjusted water pump developed by the Shanghai General Electrical Power Equipment Repair and Manufacturing Plant, long-term operating tests showed that it functioned stably and reliably and provided excellent regulation and outstanding energy conservation results, being capable of saving 11,200 kWh of in-plant consumption,equivalent to 4 tons of standard coal, every year as compared with the earlier electrically powered water pump. Recently, in order to increase the superheated steam temperature in the 670 ton/hr boiler of a 200,000 kW unit, the Jingxi power plant conducted tests and made improvements, then put a flue gas recycling unit back into operation, increasing the reheated steam temperature by 20-30° and decreasing the unit's coal consumption by about 2.5 g/kWh, thereby eliminating electricity consumption by the recycling blower and higher coal consumption resulting from decreased boiler efficiency. Coal consumption for the entire unit was decreased by 1.4 g/kWh, making it possible to save about 1,500 tons of standard coal a year. It can be seen from the circumstances described that provided the masses can be thoroughly mobilized and analysis of energy consumption intensified, there is great potential for energy conservation.

After a 25,000 kW condenser-type generator unit was converted to bled steam heat supply and power generation at the Shenyang power plant, the plant began central supply of heat to 14 nearby industrial enterprises, putting an end to the use of 45 small boilers owned by the enterprises and 30 smoke stacks, thereby not only lessening pollution of the city's environment, but decreasing flyash discharge by 9,000 tons a year and making possible a saving of 40,000 tons of standard coal in comparison with decentralized heat supply. Recently the plant has been adding a new heat supply unit which when completed will provide all the steam required by 22 plants and will provide heat to an area of 2.4 million square meters at a steam supply rate of 300 tons per hour, thus resulting in the closing down of more than 100 small boilers and a decrease of 60 smokestacks (it will be possible to decrease the amount of coal consumed in power production from 500 g/kWh and to save 100,000 tons of fuel oil which the enterprises would have used in their own boilers, as well as 100,000 tons of coal used for heating in the winter. The conservation results from centralized heat supply are striking, and industrial cities with a long heating period in the winter should pursue this approach especially actively, in combination with modernization and conversion of medium and low power units.

Following the approach of attaching importance to even small quantities in energy conservation, the various electrical systems have carried out general surveys, and the East China power system has adopted a three-level management approach to grid losses, and has actively pursued an energy conservation criticism movement; by loss accounting at every level in the electrical supply lines and by conducting a general survey, last year it recovered 3.6 million kWh of electrical energy that would have been lost. By striving to utilize reactive power, adding power capacitors, adjusting transformer connections and the like, this system recovered a total of 600,000 kvar of reactive power, assuring that the average voltage at the network monitoring points would meet standards during peak load, and thus making possible a saving of 100 million kWh. Line losses in the northeastern grid dropped by 0.61 percent, resulting in a saving of 180 million kWh.

Although the power industry had great achievements in conversation during 1980, its technical and economic indicators still fall far short of those in the developed industrial countries, and we must acknowledge that much latent potential still remains. As regards the energy consumption levels of the country's power industry, if the coal consumed in power production could be decreased by 1 percent from the current level (i.e. by 4.5 g/kWh), it would be possible to save 1.35 million tons of raw coal a year; if the line loss rate in the power grid could be dropped by 1 percent (in absolute terms) from its current level, it would be possible to save 3 billion kWh on power losses. Accordingly, we must work out an overall energy conservation plan which is based on the specific circumstances of our country's power industry and must strive to quickly attain or approach the power consumption figures for power production units of the same type in industrially developed countries, thereby making the requisite contribution to modernization of our country's power industry.

EAST CHINA POWER OFFICE REPORTS 1980 CONSERVATION RESULTS, SETS 1981 TASKS

Beijing DIANLI JISHU [ELECTRIC POWER] in Chinese No 6, 5 Jun 81 pp 3-8

[Article by East China Power Industry Management Office: "A Summary of Energy Conservation During 1980 and Organization of Conservation Work for 1981"]

[Text] I. The power plants subordinate to our office had an annual power output 6.7 percent higher than in 1979; the coal consumption rate was down by 11 g/kWh from the 1979 figure, resulting in a saving of 453,000 tons of standard coal; in-plant power consumption was down by 0,15 percent from 1979, a saving of 66.32 million kWh. The extra electricity generated and fed into the grid as a result of the savings of raw coal and in-plant power consumption totaled 1.225 billion kWh, and this, together with increased generation of hydroelectric power, met the requirement for added electrical power generation from industrial uses in 1980 and fulfilled the assignment to "realize increased output through conservation." The line loss rate throughout the grid in 1980 was down by 1.12 percent from 1979 (absolute value), and the saving was 479 million kWh.

At the beginning of 1980, this office conducted an "Increase Output, Conserve, Increase Revenues, Decrease Expenditures" movement focused on conservation, and implemented conservation directives and specific measures down to the level of individual plants, shops (or shifts), teams and individual workers. The specific work done during the year was as follows:

A. Incremental-cost Load Scheduling Throughout the Grid, Increased Hydroelectric Power Production, a Larger Percentage of Power Production by High-Pressure Units

At the beginning of 1980, in the process of economic load scheduling between hydroelectric and fossil-fueled generating plants we had to bring the water level in the Xin'an River Reservoir, which had been regulated for many years, to a normal level so as to decrease the water consumption rate; in addition, we had to quickly master the water situation at the Fuchun River generating plant, which uses runoff, so as to minimize water losses. Objectively, rainfall was rather concentrated in 1980, and this in addition to economic load scheduling between hydroelectric and fossil-fueled generation resulted in a larger hydroelectric power output than in 1979, equivalent to a saving of 700,000 tons of standard coal (not included in the coal conservation figures given above). At the Xin'an River Reservoir the stress was laid on storing water, and a record water level 14.64 meters above the 1979 maximum was achieved, resulting in a decrease in water consumption from 6.39 to 5.4 m^3/kWh; the water utilization rate at the Fuchun River generating plant's reservoir reached 100 percent, and power output increased by 390 million kWh over 1979.

In the first quarter, the fossil-fueled plants under this office began economic load scheduling on the basis of incremental coal consumption rates in the main units, and in March the number of plants using incremental-cost and economic load scheduling was increased from 7 to 11, in addition to which computers began to be used to produce daily nonreactive load curves for these 11 generating plants on the basis of incremental coal consumption rates, which were issued to the plants for implementation, resulting in a saving of more than 80,000 tons of standard coal over the year. Starting in March, the Yangshupu, Zhabei, Minhang and Wangting fossil-fueled plants under this office began to close down their medium and low pressure boilers promptly in periods of low demand, starting them again in the morning; the number of boilers stoppages and restarts in 1980 reached 4,375. Medium and low pressure units generated 1.25 billion kWh less electricity than in 1979, and this, in addition to the commissioning of a new high-pressure units and a decrease in the number of temporary repairs on large units, resulted in an increase of 2.2 billion kWh generated by high-pressure units, thus increasing the share of electricity generated by the high-pressure units and saving an estimated 189,000 tons of standard coal. In order to increase the power output of its Jianbi, Nanre and Xuzhou main plants, the Jiangsu Province Electric Power Office ceased power production at its 34,000 kW high-coal-consumption railroad power station and completely shut down small units, with capacities of 8,000 kW or less, at the Taizhou, Quanhu and Xuyi power plants. The Gaochun and Huaiyin plants were either shut down completely or operated in only two shifts and shut down at night, with the result that the percentage of electricity produced by high-pressure units province-wide increased to 76.4 percent from the 1979 figure of 72.4 percent, yielding a saving of 71,000 tons of standard coal.

In addition, in order to make full use of the excess capacity of the high-efficiency heat supply unit at the Jinshan Petrochemical Combine's heat and power plant, this office concluded an agreement with the plant which was beneficial to both sides. In 1980 our office shut down low-efficiency, medium-pressure units in the system and had the petrochemical plant's power station generate power in their place; it provided 191 million kWh, saving 300,000 tons of standard coal for the country.

B. Implementation of State Energy Policy and Energetic Reduction of the Burning of Oil

In 1980 this office's actual oil combustion figure was over 4.1 million tons, a decrease of more than 290,000 tons from 1979 because of the Zhenhai power plant's newly-commissioned 125,000 kW oil-burning unit, in 1980 the Zhejiang provincial office had an increase in oil consumption amounting to 168,000 tons compared with 1979; the Jiangsu provincial office decreased oil consumption by 77,100 tons, and Shanghai's subordinate power plants decreased oil consumption by 383,000 tons). The main measure adopted was that starting in the fourth quarter of 1979, the Yangchang, Xiaguan and Minhang power plants gradually converted four oil-fired boilers which consumed a total of 580 tons per hour to coal. The Yangchang and Minhang plants built and commissioned two new coal-fired boiler units with a total consumption of 620 tons per hour; during the period when hydroelectric power production was up, medium and low pressure oil-fired boilers were shut down whenever feasible or used as little as possible; during the "exclusively fossil-fired load scheduling peak," the output of the 125 kW oil-fired unit was cut down at night to 60-80 kW, and the output of the 300,000 kW oil-fired units was cut down to 220,000 kW. As a result, the percentage of power generated by coal in the plants subordinate to this office increased to 37.4 percent in 1980, an increase of 2.7 percent over 1979, and oil combustion was decreased by more than 380,000 tons. In addition, in order to consolidate their coal burning, the Wangting, Xiaguan, Jianbi and Wujing power plants worked hard to decrease auxiliary fuel oil consumption. For example, in connection with major and minor repairs, combustion belts were installed in the boilers of the medium and low pressure stations at the Wangting power plant, the combustion nozzles were adjusted, the chemical testing and analysis of coal, coal classification and combustion regulation were strengthened and the like, so that the burning of oil was gradually stopped; by the end of the year the medium-pressure stations were burning exclusively coal, with the result that oil consumption was decreased by 38,000 tons from 1979. By regulating combustion, the Xiaguan and Jianbi power plants decreased the amount of auxiliary fuel used. The Xiaguan station also took advantage of the low nighttime demand to cut back on or stop the oil-burning boilers, with the result that the two plants decreased their oil consumption by 35,000 and 41,000 tons respectively.

C. Energetic Improvement of Large Generating Units to Achieve Stable, Full-Capacity Generation

The East China power network's existing intermediate-reheat units account for about 45 percent of the total fossil-fueled capacity in the grid. Stable, full-capacity generation in these units is of great importance for the entire grid, and accordingly we have consistently focused our efforts on them.

Recently the Wangting station's 300 kW unit underwent improvements and major and minor overhauls, which fundamentally solved such problems as blade breakage in the steam turbines, vane breakage in the draft fans, axle vibration, generator vibration, breakage of steam regulator valve rods, feedwater pump vibration, water leakage around the generator rotor, breakage of wires, boiler tube overheating and the like. In 1980, the plant installed a high-pressure heater of its own manufacture on a 300,000 kW unit, bringing the output back to 300,000 kW from 280,000 kW and decreasing coal consumption by more than 10 g/kWh/ The 300,000 kW unit's average operating time for the year was fully 7,691 hours.

Since November 1979, the overhaul contract system has been tested on two 125,000 kW units, the Zhabei power station's unit No 16 and the Minhang power station's unit No 8. Various improvements and problem elimination work were undertaken on these two units during major overhaul, as a result of which their quality was greatly improved and they set records of 208 and 184 days respectively of continuous operation without temporary running repairs. At the same time, our office organized competitions, exchange of experience, and comparative assessment for all of the 125,000 kW units in the power system; seven units were rated outstanding in the first half of 1980. The competition and comparative evaluation stimulated economic operation of the large generator units and improved management standards, as manifested primarily in smaller numbers of temporary repairs and a higher rate of commissioning of high-pressure heaters: the average number of temporary repairs dropped from 5.3 per unit in 1979 to 3.6 per unit in 1980, and the commissioning rate for high-pressure heaters increased from 68.1 percent in the first three-quarters of 1979 to 97.3 percent in the first three quarters of 1980, an increase of 29.2 percent, with the result that the coal consumption of the 125,000 kW power units dropped by 2.3 g/kWh.

D. Striving to Increase Generator and Boiler Efficiency

Steam turbine input steam characterisitcs, vacuum levels, feedwater temperatures and turbine and boiler efficiencies were increased to various degrees in the power plants. Under normal high load, the 125,000 kW units were changed over from floating steam pressure to the more economical fixed pressure operation. In the Huainan station's No 3 and 4 turbines, for example, the steam pressure was 133-137 kg/cm^3; the steam pressure in the Zhenhai station's 125,000 kW units is being held at 137 kg/cm^2, and the steam temperature at 540°C. After improvements were made on the Zhabei plant's No 16 high-pressure heater, the feedwater temperature rose from 220°C to 240°C. Efforts were made to bring the vacuum seals up to top standards in the Wangting power station's steam turbine shop, and the number of units at the top standards was increased from one-third at the beginning of the year to one-half. Excess nozzle and diaphragm flow area was sealed off on steam turbines Nos 3 and 8, new balance disks were installed, the copper cooling pipe on unit No 8 was replaced, and scale on the inner and outer surfaces of the copper tubing in the high temperature heaters was removed, after which the feedwater temperatures rose by 15 degrees and the efficiencies of the two turbines increased by 1.49 and 1.4 percent respectively. The Wuding power station arranged for divers to inspect the screening over the circulating pump water intake; the number of cleanings of the secondary filter was increased from two to four per shift; an access port for removing dirt from the secondary filter screen was provided; when the plastic ball cleaning system's ball recovery rate decreased, the plant carried out a cleaning and inspection of the tubes and plates; and during minor overhaul of the steam turbines, flushing of the copper condenser tubing was included among the standards, with the result that the average turbine condenser back pressure was 40.75 mm Hg for the year, down 0.77 mm from the 1979 figure, resulting in a saving of 1,026 tons of standard coal.

Combustion regulation of boilers has been strengthened, and particular attention has been paid to decreasing the carbon content of flyash from coal-burning boilers and to limiting low-oxygen combustion in oil-fired boilers. Soot blowers have been added, and accumulated soot on heating surfaces has been removed. The plugging of air leaks has been strengthened so as to decrease the flue temperature and increase boiler efficiency. In 1980, the power plants directly subordinate to this office installed 23 super-heaters and soot blowers with water-cooled walls, which in normal operation can increase the steam temperature and decrease the flue temperature by 10 to 15 degrees, increasing boiler efficiency by about 0.5 percent. Many power plants have organized combustion regulation groups, have strengthened coal classiffication, draft regulation, and chemical testing and analysis of coal and ash and the like, and the flyash carbon content and the oxygen content of the gas at the combustion chamber outlet have been decreased. For example, after a competition to decrease the carbon content of flyash at the Wangting medium-pressure power station was begun, the carbon content decreased from 5 percent to about 3.5 percent.

E. Cutting Back Energy Consumption by the Four Main Types of Auxiliary Machinery, and Making Wider Use of Energy-Saving and Modernization Measures

The various plants are continuing to make wider use of high-efficiency feedwater pumps, blowers and dust removers, and are removing one stage from pumps with excessive pressure head or machining down their impeller wheels; in addition, the blades of blowers with excessive pressure heads are being shortened. For example, an annual saving of 19.3 kWh was achieved on nine high-efficiency feedwater pumps in Anhui on which improvements were made; the saving on five pumps in Zhejiang which were improved was 1.27 million kWh a year, and that on three high-efficiency dust removers was 2.39 million kWh a year. The Huainan power station replaced the No 4 furnace's dust removers with model 5-36 high-efficiency blowers, saving 1.162 million kWh per year. The feedwater pump on boiler No 9 at the Minhang generating plant was replaced by a high efficiency unit, saving 5,000 kWh per day; the impellers on two feedwater pumps in boiler No 10 were made smaller, saving 17,000 kWh a day; and in addition a hydraulic ally-coupled speed-regulated feedwater pump produced by the Shanghai Electric Power Equipment Repair and Manufacture Combine was installed on the newly constructed boiler No 11, saving about 11,000 kWh of electricity a day. The top stage impeller wheel of the feedwater pump at Jianbi generating plant's unit No 6 was replaced by an inducer wheel, saving 4,800 kWh per day. The impeller of the Xuzhou power plant's No 4 circulating pump was made smaller, saving 3,000 kWh per day. The size of the impeller on the Sudong plant's No 3 circulating pump was also decreased, saving 1,800 kWh per day. One impeller was removed from each of two feedwater pumps at the Zhenhai plant, and from one pump each at the Huaibei and Ma'anshan plants, saving 15,000 12,000 and 1,400 kWh a day respectively. Impeller wheels were trimmed on eight blowers and suction fans at the Wujing, Huainan, Gaoqiao, Ma'anshan and Xuzhou power plants, saving a total of about 7,000 kWh a day.

Second, economic scheduling of auxiliary equipment and other measures were taken to save electricity. For example, the outlets from the two blowers on the No 3 boiler at the Jinshan power plant were cleared out, a throttle and an electrical interlock protection mechanism were installed at the blower inlet, and single blower operation saved 400 kWh a day. The circulating pumps on the Jiabei No 15 and 16 turbines had low suction, and it was necessary to use two jet pumps, but when these two pumps' suction tubes were cleared and the use of one jet pump was discontinued, 2,400 kWh per day was saved. During smooth shutdown of a 125,000 kW unit, after it had been cut back below 40 kg/cm^2 a medium-pressure feedwater pump was used in place of the high-pressure pump, making possible a saving of 12,000 kWh during each smooth shutdown, in addition to which it was possible to decrease friction wear on the feedwater valves, both of which circumstances were helpful in decreasing valve leakage and in uniformly lowering the gas temperature. The circulating pumps of units Nos 15 and 16 varied in electrical consumption, and after economic load scheduling was instituted, 1,000 kWh a day was saved. After the main water circulation line at the Tianshenggang power plant was cleared and the excess water from the circulating pump of the 125,000 kW unit used to supply the older plant, 1,500 kWh per day was saved; in addition, the pump impeller blade angle was adjusted to -6°, saving 1,500 kWh per day. The lead screening in the preheater for the No 8 boiler in the Minhang power plant was stretched, decreasing the air duct resistance and saving 10,000 kWh per day. The air duct cover and sealing devices of the preheater for the No 5 boiler at the Nanjing thermal electric power station were improved and the air leakage rate was decreased from 0.54 to 0.34; and a regulating grating was added to the intake of the ash remover, saving 240,000 kWh per year.

The power plants subordinate to this office decreased electrical consumption by more extensive use of new infrared technology. The Dakou, Zhenhai and Jianbi power plants also successfully test-installed a plant electric meter which was helpful in real-time monitoring.

F. Strengthening the Conservation Management System and Conservation Criticism and Comparison Activities

Encouraged by last year's first nationwide "Energy Conservation Month," all power plants and shops (or shifts) chose energy conservation leaders and responsible persons. Coal and electricity conservation groups, fuel management groups and the like were formed, and plant headquarters used monthly assignment sheets to transmit instructions and energy-saving measures down to the shop, team and individual levels, ran various competitions and figured bonuses monthly on a percentage basis. Some plants also conducted in-plant inspections and analysis. This office's subordinate units reinstated their previous mass-style activities based on identifying exemplary personnel. At the end of 1979, the various power plants subordinate to this office carried out energy utilization surveys and made a comparative analysis of actual and rated energy consumption, determined energy inputs and outlays, and developed measures for improvement, For example, Wujing power plant found that the main reason for high steam consumption was that in the past the flow area had been irrationally increased in order to increase output power, resulting in an increase in coal consumption of 7 g/kWh; piping was poorly insulated, increasing coal consumption by 1 g/kWh, the drain water removal rate was higher than the design figure, producing a coal consumption increase of 0.5g/kWh, and so on. As a result, 23 improvement steps were worked out. The Wangting generating plant's survey discovered that ten feedwater pumps in the plant had low efficiency. Seven of them have now been replaced, saving 3 million kilowatt-hours a year. They found that steam and water losses at the plant were rather high, so they successfully carried out a steam-water balance analysis and chemical monitoring, and over the course of 6 months the medium-pressure station's steam-water loss rate reached a record low of 1.4 percent. In addition to organizing a competition for 125,000 kW units, the system office also organized a competition between corresponding fuel-related operations at different directly subordinate power plants, and three plants were chosen as winners after exchange of experience and comparative evaluation. The three plants had rather outstanding results in improving the correctness of fuel calculations, in conducting acceptance testing of 100 percent of loaded and empty boats (or railcars), and in unloading directly at the plant's own wharves, thereby decreasing transport losses in transfer from one barge to another, eliminating the necessity of recovering the remaining coal, and conserving funds (800,000 yuan). The Zhejiang provincial power industry office held an energy conservation experience-exchange meeting at the Zhenhai generating plant and drew up quotas for the units directly subordinate to the provincial office. The Anhui provincial office held a technical and economic indicators conference at the Anqing generating plant for exchange of experience and discussion of evaluation methods. In August our office selected the Wujin plant and six others as the most advanced plants in energy conservation among the subordinate units, based on the State Economic Committee's "ten types of energy conservation work," "three major organizational measures" and "six main conditions for critical evaluation."

G. Conscientious Implementation of the "Line Loss Management System" and Active Promotion of the "Ten Experiences in Decreasing Line Losses"

Although the quantity of electrical energy supplied by the entire system in 1980 was up 7.1 percent over 1979, line losses were down from the previous year, saving 479 million kWh. This was owing primarily to intensified line-loss management.

At the end of 1979, a conference representing the entire power system subordinate to this office gave full financial, technical and management support to measures for decrease line losses. Starting on New Year's Day 1980, line losses throughout the system were divided into primary losses, secondary losses and supply line losses on the basis of voltage level; these were to be managed at the system office, provincial offices and local power supply offices respectively. The Nanjing, Shanghai and Hefei local power supply offices also instituted a number of instructions and made checks of the relevant departments, after which they mobilized employee energy conservation enthusiasm and implemented more than a thousand mass-style measures for decreasing line losses throughout the system, with an estimated saving of more than 100 million kWh. Second, the voltage level was raised. In 1980, the average voltage for the entire 220 kV main system at 9 o'clock was 220.9 kV, up 20.4 kV or 10.12 percent from 1979. The voltages were correspondingly raised at the 110 kV level and below, thereby decreasing line losses by about 150 million kWh. The third step was to intensify economic operation of the power grid. An effort was made to achieve local balancing of output and load in all the individual areas so as to minimize the amount of power exchanged in the power grid's tie lines. Compared with 1979, the quantity of power sent by Anhui to Jiangsu decreased by 40 percent, and the quantity which Zhejiang received from Jiangsu and Shanghai dropped by 42 percent, correspondingly decreasing line losses. The management of phase-adjustment operation of hydroelectric units was intensified: for example, in 1980 there were an average of 3 to 4 phase-adjustment units at Xin'an River station, 2 fewer than in 1979. The total annual electrical saving from these measures was 50 million kWh. The fourth measure was intensified construction of electrical transmission lines and substations and adjustment of the ratio between investments on generation and supply; investments [on power supply] in 1980 were 92.85 million yuan, accounting for 33 percent of the investment total and representing an increase over the 25 to 28 percent figure for the preceding few years, in addition to which replacement and modernization funds totaled 47 million yuan, also a higher figure than previous years. In 1980, six lines and six substations in the 220 kV circuit and large numbers of transmission lines and substations at the 110 kV level and below were completed, along with voltage upgrading, conversion and line replacement projects. It is estimated that these projects, together with those that went into operation in the second half of 1979, saved 100 million kWh. In addition, operations surveys were made, locating many instances of waste such as unmetered power use and theft and leakage of electricity and resulting in the recovery of paid power consumption amounting to 44 million kWh.

II. In 1980 it will be necessary to implement consistently the four-point policy centered on readjustment, to strengthen centralized management of the power grid, to strengthen the safety base, to pursue the "increased production and conservation" movement centered on energy conservation and to guarantee that the power grid will meet local agricultural and industrial production requirements and the people's daily-use power requirements. Below we list the ten main energy conservation measures for 1981.

A. Converting Medium and Low Voltage Units to Peak or Seasonal Generation So As To Increase the Percentage of Power Generated With High-Voltage Units

Before and after the high water season, the Minhang generating plant's 48,000 kW medium-pressure station, the Zhabei A 54,500 kW station, the Huainan power plant's 36,000 kW station and the Xiaguan power plant's 25,000 station are to be converted to peak-period or seasonal generation. In the case of oil-fueled boilers this is also helpful in decreasing oil consumption. Turbine and boiler equipment which is shut down must be overhauled and carefully maintained. It is estimated that the abovementioned measures can decrease the amount of electricity produced by medium and low pressure turbines by 680 million kWh, and that the changeover to generation by high-pressure generating units can save about 70,000 tons of standard coal.

B. Improvement of Oil-Fired Boilers, Energetic Efforts to Decrease Oil Consumption

(1) Conversion of the Wujing No 7 boiler to coal combustion was completed at the beginning of the year and the unit was phased into the system; this year oil consumption has been decreased by more than 100,000 tons. An effort is being made to complete the equipment for the ash removal system so that coal combustion will not be hindered by the ash removal problem.

(2) Energetic design work and preparations are under way for improvements on the Minhang No 9 boiler, which will be shut down in the second half of 1981; the conversion will decrease oil consumption by 50,000 tons.

(3) Design work and preparations are being made for improvements on the Wujing No 0 boiler, which will by shut down in the fourth quarter.

(4) Combustion regulation of the Minhang Nos 1, 2 and 11 boilers is being undertaken so as to minimize use of auxiliary fuel oil.

(5) After combustion becomes stable in the Yangchang No 35 furnace, the low pressure boiler will be entirely shut down, saving 60,000 tons of oil.

(6) The capacity of the Wusong substation is being increased and State Cotton Mill No 8 is being converted from 35 kV power supply. The Wusong power station's 36,000 kW generator is being converted to back pressure [5154 1090] operation, which will save 10,000 tons of oil, and further research is being done on steps to convert to the burning of coal.

(7) Work is being done at the Jianbi generating plant to alleviate blower wear, increase power output and decrease oil consumption. As early as possible, the Siaguan power plant's local load will be shifted to the new Sajiawan substation, and more small oil-burning boilers will be shut down.

C. Effective Preparation for Large-Unit Peak Laod Adjustment, Preparation for Full Hydroelectric Power Generation During the High-Water Season, and Prevention or De-Creasing of Water Waste

System peaks and valleys already differ by 1.5 to 1.8 million kilowatts, and in 1981 medium and low pressure units will be shut down. During full hydroelectric power generation in the high-water season, the large units will have to take on the task of peak load adjustment, and accordingly we must continue effective testing and modeling of the large units' load adjustment capability, for example turbine and boiler water circulation tests, tests of the speed at which fires can be increased, measurement of differences between the upper and lower wall temperatures of steam drums and the like.

We must fix the minimum power output for domestically produced 125,000 kW units and set permissible rates of change of load.

D. Intensified Reservoir Scheduling, and Expanded Incremental-Cost and Economic Laod Scheduling Between Hydroelectric and Fossil-Fired Plants

At the beginning of 1981, the water head at the Xin'an River hydroelectric station was 12.47 meters higher than during the same period last year. Now that the inflow is relatively large and the precipitation during the rainy season has been relatively concentrated, we must arrange to generate more electricity. In order to minimize or limit water losses and to prevent the water level in the reservoir from exceeding the normal storage level, this year we must gradually increase power output before the high-water season so as to decrease the reservoir water level, while during the rainy season we must determine the quantity of electricity to be generated on a month-to-month basis in terms of water inflow and gradually increase the level in the reservoir. During the period when the reservoir supplies water we must stringently control the amount of power generated so as to assure that at the end of the year there will still be a certain amount of water available for power production. At the Fengchun River hydroelectric plant, the amount of power generated will be decided in terms of water inflow; when there is a rather large inflow the Xin'an station will decrease its output so as to decrease the water inflow pressure on the Fengchun River station, and in addition the fossil-fired stations will suitably decrease their power output so that the Fengchun River station can operate at full output and minimize water losses. Other hydroelectric power stations will strive to use irrigation water to generate more electricity, and during the high-water season they will strive to support the flood control departments, adjust their output in rational fashion, and do everything possible to minimize water loss by generating electricity so as to decrease the water level.

The key to successful reservoir scheduling is a timely grasp of hydrological and meteorological changes and the provision of timely, correct reports on the water situation; accordingly, all hydroelectric plants and load scheduling bodies at all levels must make a major effort in these two kinds of work.

Determination of daily power output requires that the hydroelectric plants perform fully their function of peak and frequency regulation and their role as an emergency reserve. Accordingly, the Xin'an and Fuchun River plants must achieve good incremental-cost water consumption characteristics for the hydraulic turbine generators and for the plants as a whole so that they can use incremental-cost and economic scheduling of the individual units in the plant and develop incremental-cost and economic scheduling between hydroelectric and fossil-fired generation in the entire system. The Xin'an River and Fuchun River plants must also find ways to increase the degree of automation of hydrologic recording and use computers for economic reservoir adjustment.

As regards fossil-fired power generation, the provincial offices must convert some medium and low voltage units which will not require major engineering effort and will not affect local loads to peak or seasonal generation, or shut them down and carefully mothball them so that they will not be competing with the large units. The three provincial offices must also work out a comprehensive incremental-cost consumption curve for provincial dispatching stations and take part in system-wide economic scheduling. They must use their existing computers for incremental-cost and economic load scheduling in the provincial dispatching stations. The Wujing, Nanre, Jinshan and Yangshupu heat and power stations must determine all the thermodynamic characteristics of the heat supply units so as to pursue incremental-cost load scheduling for the plant's heat supply units.

In addition to publishing daily load curves, the general dispatching office should use computers to calculate and issue daily load rate and coal consumption rate information so as to improve the correctness of incremental-cost scheduling, and must investigate reactive power economic load scheduling for the Xin'an River and Fuchun River power plants and the Huaibei and Xuzhou long-distance plants.

E. Maintaining Cleanliness of Inner and Outer Heat Receiving Surfaces* of Boilers

Acid cleaning of boilers should be undertaken during major overhaul when it has been determined that there are excessive scale buildups in the tubing and on the walls, and spcialized acid cleaning services must be organized and intertrade boundaries overcome in order to promote industrial acid cleaning of boilers and save fuel. Boilers should be rationally provided with sufficiently effective soot removal blowers, and long and short tube-type soot blowers should be developed. The generating plants in Shanghai should learn from the experience of using existing soot removal equipment in the Nanshi power plant No 10 boiler, the Wangting No 13 boiler, the Yangchang No 31 boiler and the Minhang No 10 boiler (tight sealing of boiler drive mechanism) and make full use of the capabilities of ash* blowers already installed on boiler units. The various power plants should take advantage of overhauls to identify soot accumulation locations and should install a full set of soot blowers in the first half year, in addition to which they can follow Jianbi and Jinshan power plants' steel ball dust removal experience in boilers with tubular type preheaters.

In 1981 the power plants directly subordinate to the office will acid-clean 15 boilers, with an estimated improvement of 0.2 percent in boiler efficiency. The three provincial offices must also determine the number of boilers which require acid cleaning and draw up an acid cleaning plan. Waste acid must be suitably disposed of so that discharge standards are complied with. The experience of using ferrous sulfate to plate a coating on condenser tubes should be used more extensively, as should leak prevention experience. The Xuzhou and Huaibei power plants should promote sodium triphosphate treatment of circulating water and should install plastic dehydrators in cooling towers, eliminate condenser scale and decrease losses of cooling water.

F. Continued Improvement of Large Generating Units and Elimination of Bottlenecks

Increasing the utilization rate of 300,000 and 125,000 kW generator units and strictly limiting the power generation and operating hours of medium and low voltage units are important energy conservation measures. The Wangting and Jianbi 300,000 kW units' high pressure heaters will need to be installed at an early date. To make the generator units achieve their rate output, unit coal consumption should be decreased by 12 g/kWh, saving about 2,548 tons of coal a month. The Jianbi generating plant making an energetic effort to solve the problem of the three Jian-Chang loops before the high-water season so as to save 25,000 to 30,000 tons of coal. Because of the problem of circulating water escaping from the tubes in the newly constructed Minhang No 11 generator unit, the plant must make an energetic effort to install new drainage tubes so that the generating projects that have been put into operation will be able to produce their full economic benefit. In 1981 the three provinces will repair the final section heating surfaces of six 400 ton-per-hour boilers; by assuring quality and eliminating temporary repairs, they must strive to decrease the amount of work time and thereby increase the large units' utilization rate.

G. Continuous Expansion of the Use of High-Efficiency Fans and Water Pumps and Effective Fixing of the Design for the Auxiliary Equipment of Large Units

This office has a total of 289 blowers, suction fans and dust removers, of which 42 are axial-flow and 55 are centrifugal types. Most of the high-efficiency fans used in the past were of the centrifugal type, but because after the power grid recovered normal-frequency operation and the boilers returned to rated output, the nominal capacities of the fans and water pumps which had been converted were too large, so that it was necessary to make surveys and design new high-efficiency blowers and water pumps with reference to the actual form of operation.

An energetic effort whould be made in effective fixing the design of auxiliary equipment for 125,000 kW units: Wujing is the experimental unit for blowers and suction fans, while Minhang is the experimental location for dust removers; after the designs are finalized they will gradually be put into more extensive use. The Minhang generating plant is the experimental location for water pumps, and the efficiency of hydraulically-controlled feedwater pumps is gradually being improved. The use of circulating water vacuum pump deaerators is being studied.

H. An Effort to Automate Completely the Startup of Combustion in the Boilers of Large Units

The Minhang plant's No 10 boiler is being used as the experimental location for this effort, and after experience is summarized this approach will be put into use throughout the system; it may increase boiler efficiency by more than 0.2 percent. The Wangting plant's No 12 boiler is experimenting with use of a computer with its No 12 boiler to calculate efficiency and for automatic combustion regulation.

I. Continued Strengthening of the Technical Management of Energy Conservation

Energy conservation management requires persistent implementation of the "ten types of work" issued by the State Economic Committee and the document "Conditions for Coal and Electricity Conservation in the Power Grid and in Fossil-Fired Plants." We must start by strengthening the leadership and staffing of energy conservation work, and must transfer and fully replace personnel who are not suited to their positions. The assigned energy conservation indicators and measures must be analyzed and implemented down to the shop (or shift), team and individual levels. An effort must be made to see that measuring and testing procedures are in place within 2 years, that coal scales and oil meters are installed and calibrated, that correct measurements, calculations and evaluations of plantwide and individual station coal and oil consumption are made; the current practice of calculating coal consumption by the reverse balance method and of closing coal consumption accounts in terms of the number of trays remaining at the end of the month must be changed (the reverse balance calculation method may be used only for technical analysis).

J. Do Everything Possible to Decrease Line Losses

Construction of the power network at all levels must continue to be intensified, reactive power must be compensated, work on transmission, distribution and consumption must be increased, and voltages must be raised to the normal levels. Economic reactive power operation throughout the system must be pursued, and the Xin'an River hydroelectric station and the 110 kV Shangyu power station should be used as test points to investigate optimal control of reactive power and voltage at power plants and substations. Low-loss distribution substations should be used, and the replacement of low-silicon steel switchgear should be accelerated. Theoretical line loss calculations and operational surveys should be conducted and continued improvement should be made in the management of electric metering.

SHIJINGSHAN POWER CORPORATION ENERGY CONSERVATION MEASURES DESCRIBED

Beijing DIANLI JISHU [ELECTRIC POWER] in Chinese No 6, 5 Jun 81 pp 8-10

[Article by Shijingshan Power Combine: "Strengthen Enterprise Management, Strive to Conserve Energy"]

[Text] We are an electric power enterprise which runs three power plants and five power stations with 21 generating units of various types and with a total generating capacity of 1.06 million kW. In recent years, as a result of intensified enterprise rectification and management, we have pursued a coal and electricity conservation movement while maintaining safe power production. In 1979 we drew up a list of 38 power conservation measures and saved more than 97,000 tons of coal for the state. In 1980 we made further efforts to use latent conservation potential in the equipment and further decreased various consumption indicators. Our specific coal consumption for the year was 393 g/kWh, 3 g/kWh lower than the plan figure, which gave a saving of more than 20,000 tons of coal. The 100,000 kW unit at the Gaojing plant and the 200,000 kW unit at the Jingxi generating plant maintained their specific coal consumption at advanced national levels for the type of equipment in question.

1. Strengthening Operations Management

In order to assure safe and economical operation of the equipment and to save energy, we adopted the following measures.

A. Effective Management of Boiler Unit Operation in Order to Maintain Long-Term High-Efficiency Boiler Operation

The boiler operating personnel at the Gaojing plant conscientiously implemented the coal and electricity conservation regulations, maintained conscientious inspection, ash sampling and adjustment during operation, and strove to maintain a stable steam temperature, a stable water level, and stable load adjustment. The chemists carried out continual tests of the coal powder fineness and furnished data for combustion regulation. At any time when boiler combustion conditions were incorrect, heat testing personnel made timely on-the-spot draft measurements, and they and the operating personnel jointly regulated combustion. As a result of intensified combustion unit operation management and close coordination between the relevant shops and specialists, the boiler efficiency in 1979 was 93.38 percent, exceeding the average design parameters for each boiler (91.86 percent), and saving more than 25,000 tons of standard coal.

B. Intensified Analysis of Operations in Order to Make Equipment Operation More Economical

The heat economics groups of the combine and its individual plants constantly analyzed equipment operating conditions and problems which arose during operation, located the problems, proposed measures and jointly solved the problems. For example, the makeup water rate in the Gaojing plant's boilers was somewhat higher than in the same period in the preceding year; the personnel of the heating economics group made a thorough analysis of the reasons, along with the operating personnel, and solved all of the problems which were found, bringing the makeup water rate down somewhat. In 1978, there were 348 boiler and turbine stoppages and restarts, 142 more than in 1977, and the makeup water rate was down 2.44 percent from the 1977 figure of 2.56 percent. In 1979 the Gaojing power plant undertook the task of peak regulation; there were 670 boiler and turbine stoppages and restarts, 2.3 times as many as in 1977, and the makeup water rate stayed at 2.50 percent. In 1980 there were 1,035 turbine and boiler stoppages and restarts, 4 times as many as in 1977, and the makeup water rate was 2.61 percent, which still met the Ministry of Electric Power's coal and electricity conservation standards (2 or 3 percent).

C. Holding of Competitions, and Conservation of Boiler Ignition Oil

Since the Gaojing plant organized the operating personnel for a competition to save boiler ignition oil in May 1979, the personnel have constantly summarized their operating experience and had had outstanding results in conserving ignition oil. In 1978 there were 149 furnace startups, consuming 776 tons of oil, an average of 5.14 tons per startup (including oil used to assist combustion), while in 1979 and 1980 the startup figures were 298 and 496 times respectively and the average ignition oil consumption dropped to 1.07 and 0.528 tons per startup respectively. Currently the hot-furnace ignition oil consumption for a 220 tph [ton per hour] boiler is 0.1 tons per startup, and the cold-furnace ignition consumption is 1.0 tons per startup, while for a 410 tph boiler the ignition oil consumption (cold furnace) is 2 tons per ignition.

D. Intensified Boiler Combustion Regulation Testing to Assure Optimal Oxygen Content of Flue Gas

The Jingxi power plant made solving the problem of black smoke emissions during fluctuation of boiler loads and during the shutdown and startup process one of its major coal and electricity conservation topics, and specialized personnel and operators made joint combustion regulation tests which showed that the optimum flue gas oxygen content was 2 percent, in addition to which they worked out an effective operating method: during increasing loads they adjusted the draft first and then the oil, and when the load was decreasing they adjusted the oil first and then the draft. In this way good combustion conditions were maintained in the furnace, and there were virtually no black smoke emissions from the smokestack.

E. Intensified Combustion Management and Effective Oil Monitoring Work

The 670 tph boiler at the Jingxi plant burns heavy oil, and in the past no one had any idea whether there were deficits in oil received. Starting in 1978 a combustion oil monitoring system was established and kept in continued operation. In the first half of 1977 the oil supply deficit rate was 3.16 percent; timely establishment of relations with the oil supply units and frequent representations to them resulted in confirmation of the situation. In 1980 there was virtually no deficit, and the plant's coal consumption (calculated equivalent of oil consumption) was down 7.6 g/kWh from the 1979 figure.

2. Intensified Equipment Management

In recent years, we have persisted in carrying out comprehensive survey-type thermal efficiency tests before each major unit overhaul, and have made elimination of energy-wasting equipment defects during operation a key aspect of coal and electricity conservation work.

At the time of each major overhaul, the turbine inspection and maintenance teams persist in meeting the overhaul quality standards and deal conscientiously with even the most minor aspects, such as scraping clean the connecting surfaces of the steam cylinder and diaphragm to make sure that the gaps meet the standards, adjusting the gaps in the axle seals and diaphragm steam seals to within acceptable tolerances, using a sand blaster and gauze to thoroughly clean scale from the diaphragm and the blades, and so on. As a result, overhaul of a 100,000 kW unit resulted in an increase of 0.45 to 0.79 percent in boiler efficiency, so that each unit's coal consumption fell by 4.2-7.4 kg/kWh.

During each overhaul, the boiler overhaul teams must thoroughly clean the heating surfaces, completely ream out the air preheated tubes, assure that there is no air leakage in the plenum or walls, recondition burned-away combustion nozzles and the like. In 1980, following an overhaul of the Gaojing plant's No 6 boiler, efficiency was increased by 0.82 percent. Because of scale accumulations on the water cooler walls, acid cleaning was carried out on the water side of the cooler walls of six boilers, making a contribution to safe and reliable boiler operation.

Because the inspection and maintenance personnel have combined economy with safety in putting quality first, have accorded proper importance to the quality of their procedures, and have devoted attention to day-to-day maintenance, modernization and improvement. they have continuously improved the equipment conditions and have greatly decreased the number of temporary turbine and boiler stoppages for overhaul. For exmaple, in 1977 the six 100,000 kW units at the Gaojing station were stopped 37 times for temporary repairs, while in 1980 the figure dropped to 16 times; in 1977 turbine and boiler downtime was 1,664 hours, while in 1980 the figure had dropped to 219 hours.

Intensified equipment management and improved equipment overhaul and maintenance quality have lengthened the time between overhauls, decreased the number of temporary repairs and shortened the time required for major and minor overhauls and temporary repairs, creating the conditions for production of more electric power.

3. Organizing Mordernization, Exploitation of Latent Potential, and Improvement

In order to assure safe, full-capacity, reliable operation of the units, all of the plants and stations have organized three-way technical task groups which include workers, technical personnel and cadres, have mobilized the masses, and have carried out modernization, conversion and full-utilization activities, achieving rather good results in energy conservation.

A. Keeping Plastic Ball Cleaning Apparatus Operating Normally

For many years the Gaojing power plant's steam turbine condenser tubes have had a serious scale problem, and the traditional labor-consuming method of having the workmen ream out the copper tubes, carrying out acid cleaning, and installing circulating water flue gas treatment equipment have been tried, but these steps were incapable of achieving a substantial solution of the scale accumulation problem in the condenser tubes. All of the plant's 600,000 kW generation equipment proved capable of supporting only about a 500,000 kW load during the summer when the water temperature was high, and accordingly starting in 1976 the plant decided to install two filter screens and a plastic ball cleaning system. After repeated improvements over the course of a year and a half, by June 1977 continuous plantic ball cleaning of condenser tubes had been tested on six 100,000 kW generator units, and more than 3 years of essentially normal operation have given a ball recovery rate of over 95 percent. During a windstorm in the winter of 1977, large number of leaves and grass passed through the protective grating into the second filter so that it became clogged and the ball cleaning equipment was temporarily disabled. In the summer of 1980 there was a serious moss problem, and the ball cleaning system suffered another serious breakdown. Because leadership at all levels concerned themselves with the problem and quickly organized a repair group, normal operation of the ball cleaning system was assured. In 1980 boiler shutdowns were utilized to carry out 22 ball removal operations on 12 condensers on 6 turbines, removing a total of 6,510 balls which were stuck in the copper tubes, and assuring normal operation of the ball cleaning system which can make possible a saving of 18 tons of standard coal a year.

B. Decreasing the Length of Repair Stoppages of High-Pressure Heaters

When high-pressure heaters leak and are withdrawn from operation, unit coal consumption goes up by 7 to 10 g/kWh. In order to assure that the quantity of feedwater passing through the heaters was constant and did not exceed the design figures, the Gaojing power plant added a connecting line to the main lines exiting from the feedwater pumps between units so that the point at which the main feedwater lines were paralleled was moved from the heater output to the its inlet. In order to decrease heater leakage and increase the utilization rates, the steam turbine overhaul crew continuously summarized experience, improved the quality of their overhaul procedures and decreased the stoppage time required for overhaul. In 1976 each high-pressure heater overhaul at the Gaojing power plant required an average stoppage of 115.8 hours; in 1979 the figure was 40.5 hours and in 1980 23.4 hours. The number of internal leaks in the heaters also showed a clear decline. In 1976 the utilization rate was 88 percent, in 1979 96 percent, and in 1980 97.8 percent. The 1979 utilization rate for the Jingxi power plant's 200,000 kW unit high-pressure heater was 73.1 percent, which was raised to 96.7 percent in 1980. Both plants achieved the advanced operating characteristics (95 to 98 percent) requested by the Ministry of Electric Power).

C. Addition of Advance Preheaters to Prevent Ash Clogging of the Air Preheaters

Because the input air temperature at the Jingxi power plant's air preheater was low and there were serious condensation and ash accumulation problems, it was manually reamed out from top to bottom during major overhauls. The working conditions were poor and the work extremely toilsome, and even when the procedure was modernized and water under a pressure of 13 kg/cm^2 was used to wash the unit out from top to bottom, it was still necessary to ream out each of 3,000 blocked preheater tubes during each major overhaul, which involved a large quantity of work. As a result, starting in 1978 advance preheaters were installed on six turbines, and the condensation corrosion and ash accumulation problems in the preheater low temperature stage were essentially solved, so that excellent heat transfer efficiency was constantly maintained.

D. Experimental Use of Flue Gas Recycling Equipment to Increase Reheat Temperatures

The 670 tph vertical cyclone furnace at the Jingxi plant was originally provided with a flue gas recycling temperature adjustment device, but it could not be used; in order to increase the economy and safety of the unit's operation, in cooperation with brother units the plant put it onto trial operation in December 1980 during overhaul and conversion work, which solved the problems of decreased heat absorption by the convective heating surfaces and excessively low first and second stage steam temperatures and economizer outlet temperatures resulting from a drop in the flue gas temperature at the outlet of the rear fuel oil combustion chamber (originally designed to burn Jingxi smokeless coal); as a result the average reheater temperature increased by 25°C (with installation of a recycling blower), and it was possible to decrease coal consumption by 1.49 g/kWh, saving 1,640 tons of coal a year.

E. Some Other Energy Conservation Measures

In recent years the Gaojing power plant has carried out improvements on 15 dust removers, three blowers and two feedwater pumps, making possible annual savings of 4.2 million, 600,000 and 3.00 million kWh respectively. A hydraulic jet was used to replace an ash slurry pump in the chemical water settling system, making possible a saving of 30,000 to 40,000 kWh of electricity each year. Use of pressurized water from the outlet of a circulating pump to replace a wash pump made possible an annual saving of 10,000 kWh. In order to decrease coal consumption, an expander was added to the turbine final stage steam outlets; a bled steam source was replaced by a low-pressure steam source; and a header was added to the outlet of the condensate pumps. In order to assure that the generator would achieve the desired output and to increase hydrogen pressure operation, they adopted measures such as decreasing hydrogen leakage.

The Jingxi power plant's 200,000 kW units constantly operate under low load, and in order to improve their operating economy under these conditions, single-speed suction fans were replaced by two-speed fans, resulting in a clear electrical energy saving. The plant also improved the water removal method in the large oil tanks, saving about 35,000 kWh of electricity a year.

GENERAL

METHOD OF TECHNICALLY EVALUATING ECONOMIC PROJECTS DESCRIBED

Tianjin KEXUEXUE [SCIENOLOGY] in Chinese No 3, 1981 pp 23-24

[Article by Wang Guoxing [3769 0948 5281] of Jiangxi Provincial Scientific and Technological Commission: "Probing Into the Analysis of Technical Economy Carried Out in Development Study"]

[Text] Science and technology must be closely integrated with economic construction in order that the projects under study can be technically advanced and economically rational. Therefore, a study of the rationality, speedy action and correctness of our policy decisions on science and technology is urgently needed, particularly in conducting demonstrations and analyses of certain important technical and economic problems in our country.

This article will introduce the concept of value engineering as a method of comprehensive qualitative and quantitative analysis in development study. Its main feature is the combination of simple mathematical calculations with tangible demonstrations and analyses. This method can be used for technical and economic forecasts before the beginning of the study and can serve as reference data for policy decisions with a view to obtaining better results in scientific research. It can also be used for a more objective technical and economic evaluation of the result of the research.

Value engineering is generally conducted according to the following procedure:

1. Work out various alternate plans and ascertain their technical and economic indexes;

2. Prove and analyze the tangible factors that may influence the various plans and select the corresponding technical and economic parameters;

3. Work out the corresponding formulas for mathematical calculations together with numerical values to be substituted;

4. Carry out a comprehensive analysis and demonstration of the internal and external advantages and disadvantages from various technical and economic aspects, compare the plans and finally choose the best one;

5. Conduct research, design, trial production or experiment, and constantly followup and examine the projects under research.

The mathematical form of value engineering in research is expressed as:

$$V = E.Ka.Kv.Kl.Kd.Ke \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

Here V stands for value engineering; E, for economic benefits; Ka, for progressiveness coefficient; Kv, for feasibility coefficient; Kl, for dependability coefficient; Kd, for suitability coefficient; and Ke, for job opportunity coefficient.

Value engineering can be used for technical or economic forecasts on the projects under research, or to compare them with one another. It can also provide reference data for policy decisions in tapping potentials and renovating or transforming production enterprises; or for technical or economic evaluations of the result of research.

Economic benefits refer to the amount of economic gain and can be expressed as follows:

$$E = 1 - W \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

Here 1 is the anticipated gain; W, the research expenditure.

It is obvious that the greater the economic benefits, the more acceptable will be the research project.

The anticipated gain in (2) means income from the expected increase in sales or the expected savings in production (to be accounted for annually or to be accumulated year after year). This numerical value can be calculated from the anticipated performance of the project under research. The research expenditure can be calculated as follows:

$$W = K(Wr + Wm) \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (3)$$

Here W stands for research expenditure; Wr, for labor consumption (or living labor) including the wages of the research personnel, expenses for inspection travel, design expenses, and so forth; Wm, for material consumption (or materialized labor) including materials, elements, parts, extra installations and equipment, trial production, processing expenses, and so forth; K is the coefficient of scientific research and management expenses. Generally, it is expressed as K = 1.1 - 1.3, in consideration of scientific research and management expenses which combine to form the whole research expenditure.

Progressiveness refers to the degree of superiority of the technical function of the project under research. There are still divergent views and disputes on this question. According to the viewpoint of the "high-grade, precision and advanced schook," people can blindly strive for "advanced world levels" in disregard of objective conditions and production costs. According to the viewpoint of the "suitable technology school," people may one-sidedly stress suitable value and confuse scientific research with ordinary "tapping potentials, renovation and transformation." These people may also insist on a reasonable technical standard, but this standard must be based on what is within our power. If the progressiveness coefficient expressed by Ka is divided into "low, medium and high" grades, then it should be correspondingly expressed as Ka = 0.8; 1.0. and 1.2. This will enable us to consider the degree of superiority in selective value engineering.

Feasibility. This refers to the possibility of success or failure for the project under research. It is commonly called the degree of certainty. A feasibility analysis means a calculation of the risks involved. Feasibility varies according to different characteristics in different projects. In conducting research, feasibility is greater when similar samples or experiences at home or abroad are available for reference, and the risk likely to be encountered is less. The analysis of feasibility is mainly based on the availability of scientific and technological data, the skill of research personnel, the extent of certainty in tests and experiments, facilities for processing and trial production, the performance of elements, spare parts and auxiliary equipment and their availability, and many other factors. Accordingly, Kv is used to denote the feasibility coefficient. Thus Kv = K_1, K_2, K_3, K_4 and K_5. The numerical values can be obtained from Table 1.

Table 1.

Name of coefficient	Symbol	Numerical Value
Availability of data	K_1	0.8-1.1
Skill of research personnel	K_2	0.8-1.1
Certainty of tests and experiments	K_3	0.9-1.1
Processing and trial production	K_4	0.9-1.1
Supply of elements, parts and equipment	K_5	0.9-1.1

Table 2.

Name of coefficient	Symbol	Numerical Value
Breakdown frequency	K_1	0.9-1.2
Sustained breakdown	K_2	0.9-1.2
Average life	K_3	0.9-1.1
Durability	K_4	0.9-1.1
Effectiveness	K_5	0.9-1.1

Table 3.
